In case of severe frosts there will be the convenience of a frame for keeping half-hardy plants in over winter, had better place round it some dry Fern, Furze, or straw litter, recommended to be collected many days ago, for the purpose of excluding frost. Cover the glass with a dry mat, and shaking some fine, a little hay or straw over, secure with another mat. When the frame is undisturbed for a morning, let the under mat that may be added into some place where it will be kept dry. Half-hardy annuals, Pelargoniums, and such like plants, may be effectually protected during severe frosts. Keep the soil in the pots as dry as the health of the plants will admit of; and in watering, take care to scatter the water as possible. No shelter is given to the open when it can be done with safety. A dampish atmosphere stops the attacks of frost, and in dry days, when not too cold, removes them altogether. If some of the hardier varieties of Fuchsia, as Riccartonii, gracilis, &c., permitted to winter in the open ground, have their stems protected by a few inches of the Fern, and their stools covered with leaf-mould, litter, or some such material, they will survive the winter in good condition, and flower considerably earlier next year than if they had been left without any protection. Artichokes will require to have a small quantity of leaves or litter placed round their stems. Seeding of any unwanted early, should now be covered. The weather during still favourable, advantage should be taken of it for forwarding any operations that could not be attended to last month, such as the digging and trenching of vacant ground, which

[illegible] be completed as soon as possible, laying it up rough, in order that it may profit by the winter frosts. Continue to prune fruit-trees, and forward every operation of the season as much as possible.—*M.*

[illegible] state of the Weather near London for the week ending Nov. 23, 1844, as observed at the Horticultural Gardens, Chiswick.

Day	Date	Day of Month	Max.	Min.	Mean	Max.	Min.	Mean	Rain
Fri.	22	17	30.360	30.185	30.272	51	37	44.0	0.000
Sat.	23	18	30.146	30.000	30.073	55	37	46.0	0.000
Sun.	24	19	30.031	29.947	29.989	54	37	45.5	0.000
Mon.	25	20	29.918	29.808	29.863	54	37	45.5	0.000
Tues.	26	21	29.797	29.709	29.753	55	38	46.5	0.000
Wed.	27	22	29.844	29.747	29.795	55	38	46.5	0.000
Thurs.	28	23	30.110	30.000	30.055	55	39	47.0	0.000

Mean temperature considerably above that of last week.

Fri. 22. Dry; cloudy and fine; mostly overcast at night.

Sat. 23. Overcast; cloudy and fine; slight frost.

Sun. 24. Clear and frosty; fine, sharp frost at night.

Mon. 25. Dreary; foggy; fine; clear and frosty.

Tues. 26. Foggy; hazy and cloudy throughout.

Wed. 27. Mean temperature of the week 4 deg. below the average.

Thurs. 28. Dry; hazy; foggy; clear and frosty.

Table of the Weather at Chiswick during the last Thirteen, for the ensuing Week ending Dec. 7, 1844.

Day of Dec.	Aver. Highest Temp.	Aver. Lowest Temp.	Mean Temp	No. of Years in which it Rained.	Greatest quantity of Rain.	Prevailing Winds.							
						N.	N.E.	E.	S.E.	S.	S.W.	W.	N.W.
Sun. 1	50.5	39.8	44.9	7	0.22 in.	1	1	2	2	2	4	4	4
Mon. 2	46.1	36.8	41.4	10	0.51	1	1	1	2	3	3	4	4
Tues. 3	45.0	39.7	42.3	8	0.17	—	1	2	2	6	6	—	—
Wed. 4	47.5	38.8	43.2	8	0.14	2	1	—	1	6	3	1	—
Thur. 5	46.8	37.1	42.0	9	1.18	—	1	—	1	11	6	5	4
Fri. 6	46.0	39.8	41.7	12	0.80	1	1	—	1	5	7	5	—
Sat. 7	47.4	38.5	43.0	10	0.52	1	1	1	1	4	6	5	1

The highest temperature during the above period occurred on the 8th, 1827 and 7th, 1838—therm. 59°; and the lowest on the 3d, 1840—therm. 23°.

Notices to Correspondents.

BACK NUMBERS OF THE GARDENERS' CHRONICLE.—Many of the Numbers advertised last week having been since sold, we repeat the list of those which may still be had. Any subscriber who will forward to our publisher Post-office stamps equivalent to as many Numbers as are required, shall have them sent:—

1841:—1, 6, 8, 13, 14, 15, 16, 17, 18, 20, 22, 23, 24, 26, 27, 28, 29, 30, 31, 32, 51.

1842:—4, 5, 8, 11, 18, 30, 38, 42, 50, 51, 52.

1843:—9, 10, 11, 12, 13, 14, 16, 17, 18, 20, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 36, 37, 38, 40, 41, 42, 43, 48, 50.

1844:—All the Numbers for the present year; but parties are requested to complete their sets forthwith.

The Reprint of MR. PAXTON'S COTTAGERS' CALENDAR is now ready, price 3*d.* each Copy. An Index has been added to this present Edition. Parties wishing to have copies for distribution among their tenantry can have them at the rate of 25 for 5*s.*

APRICOTS.—*Querist.*—In summers like the past, the Breda ripened on a standard becomes exceedingly rich.‡

AZALEAS.—*An Inquirer.*—The following are good and distinct varieties:—viz., Indica alba, Danieliana, Addisonii, Floribunda, Gladstonesii, Jacksonii, Lateritia, Phœnicea coccinea, P. superba, Pulchra, Rosea, Splendens, and Fulgens.‡

BOOKS.—*Peckham.*—The Botanical Register, Botanical Magazine, Taylor's Annals of Natural History, Hooker's London Journal of Botany. All these are monthly periodicals devoted either wholly or partially to Botany.

CHRYSANTHEMUMS.—*J. M. S.*—These plants are very subject to sports, and it is thus that some of the kinds have been obtained. No one is able to account for such things, any more than they can tell why domestic animals are of all sorts of colours.

DISEASES.—*Priory Queen.*—Your Pelargoniums and Camellias are either too cold or too damp, and in all probability both. The spot is no doubt produced by this cause, and certainly not by insects. Either enable the plants to digest the excess of water, by giving them plenty of warmth, light, and air, or render their digestion unnecessary by withholding excessive moisture. Perhaps the drainage is bad; perhaps the ventilation of their house; *possibly both.*

FRUIT-ROOM.—*Clericus Hibernicus.*—You will find full information upon this subject in some Leading Articles at pp. 611 and 663, 1841, to which we would beg to refer you. We cannot recommend you to line the walls with Wheat-straw, because it will get mouldy, and injure the fruit. The mould of straw will inoculate the fruit itself. Beneath the slate roof, straw would be unobjectionable, because the house would probably be ventilated there, and so be kept quite dry, when mould would not be able to grow. Otherwise we see nothing to object to in your plan. The great points are to exclude light and to maintain a low even temperature, without frost.

FRUIT-TREES.—*An Amateur.*—Add to your list of Peaches the Grosse Mignonne and Bellegarde. For the late yellow Nectarine, substitute the Peterborough; add the Royal Apricot. The late Admirable is the best late Peach, when it ripens; but if your climate is not sufficiently favourable for this variety, the Bellegarde will afford the latest good supply.‡

GREENHOUSE PLANTS.—*G. H. S.*—No tender plants will live in a glass house, without artificial heat, unless the winter is mild, or they are half-hardy, as is the case with such shrubs as Acacia armata and alata, Aloysia citriodora, Azalea sinensis, Camellias, Orange-trees, Coronilla glauca, Correa speciosa, Daphne odorata, Fabiana imbricata, Hydrangeas, Fuchsias, and the hardier sorts of Cape Heath.‡

HEATING.—*An Amateur.*—Your two pits, with a surface of 40 square feet each, being intended for forcing Cucumbers, and propagating flowers, must be so heated as that much or little moisture may be fully at command. You will therefore require a boiler of the smallest description, and tanks that will allow the escape of vapour directly from the surface of the hot water, but capable of being scattered powderingly over, when moisture is not required. These tanks should be placed almost close to the walls, and below the support of the soil. A clear space of 2 inches [illegible] the sides like pits will be necessary for the communication of heat from the tanks to the space above the soil. The fuel will probably average less than ½ per week.

HUMMING-BIRDS.—*Louisa.*—*Enquirer.*—We have been informed that this is composed of camphorated spirits of wine, [illegible] with bitter aloes; but we cannot vouch for the fact.

HYBRIDISING.—*Delaware.*—Remove the pollen-cases as directed in Samuel's letter, page [illegible], a very small quantity will answer the purpose. The best means of heating a small greenhouse is by a small boiler, and a few 2-inch iron pipes. All other [illegible] are unsatisfactory. If you [illegible] to Arnott, *if you can*, as Stephenson's [illegible] will be useful.

INSECTS.—*A. T.*—The small specklings on the back of your Oak leaves are Oak-aphides, which are fatal to [illegible] vol. xxiii.—*R. S.*—Much will depend upon the greatest attention and perseverance in applying the remedies mentioned in your case. The habits of the American Blight were given in the *Gardeners' Chron.* p. 119, which will enable you to apply their destruction.—*R. W.*—Please to send direct to Mr. Curtis, 4 Glasshouse Yard, Goswell-street, as many as you can of the Gardeners' Chronicle, carefully packed inside by a piece of cork, and be will advise you. Those you sent were annihilated by pressure. Do they destroy the foliage only?—*R.*

PACKING.—*W. D.*—Pigeons' manure is excessively powerful, [illegible] quality; but it will burn [illegible] and thoroughly mixed with [illegible] will much improve it. If the soil [illegible] very adhesive, you will do the border [illegible] of mixing with it inch bones, charcoal lumps, and [illegible] old mortar, than by manure alone. Soils for vines should be very loose and very well drained.—*A Subscriber at Ulm* mixed with soapy water is a very good liquid manure, but it should never be applied during winter. The [illegible] season [illegible] which manure of this sort [illegible] it is thrown on the manure heap, the [illegible] strength in quality, provided you [illegible] it.

NAMES OF PLANTS.—*F. N.*—Specimens [illegible] Worthless—certainly not [illegible] Master Beurré; 5, [illegible] Nipple (of some); [illegible] Ingram.—*Ingram.*—[illegible] Hasdn's Imperiale; [illegible] and 3, Beurré Diel; 9, [illegible] Winter Nelis; [illegible] Fondante du Canada; 8, Franklin [illegible] Pippin; 9, Scottish Pitmaston; 11, Beauty of Kent; 12, Great Morceau.‡

PEACHES.—*Querist.*—The double blossomed Peach does produce fruit occasionally; and I am [illegible] other varieties with double flowers—the Plum for example; although in such all the stamens may depart from their normal condition.‡

PEARS.—*Querist.*—The Williams's Bon Chrétien will not ripen its fruit as a dwarf standard in this climate; nor will the Brasseur, d'Aremberg, or Colmar, succeed on a north wall.‡

PELARGONIUMS.—*A Country Curate.*—The best place to grow them in is a good greenhouse, the next best a good pit: but it must be capable of being thoroughly ventilated, and not be damp. It does not matter how it is glazed. The lops should not be puttied, but latticed well. Again, as to allow plenty of air to get in and out. The aspect does not signify. You cannot grow Geraniums well unless you keep your pit or house free from excessive damp: and if that is likely to trouble you, it will be *indispensable*. In the first instance, to drain your ground thoroughly.—*J. H.* says, that in the course of a tour he has lately made in Germany, he observed the beds of Scarlet Pelargoniums were a compact mass of the most brilliant flowers, and the growth of the plants had evidently been controlled; and he asks for information as to the mode in which this is accomplished, as the Pelargoniums in England run to growth and leaf, with here and there a straggling spike of bloom. His observations were made during the months of August and September. Dry soil, a dry atmosphere, and a hot sun are the causes of the condition of the German Pelargoniums. Our garden ground is often much too rich and moist for them.

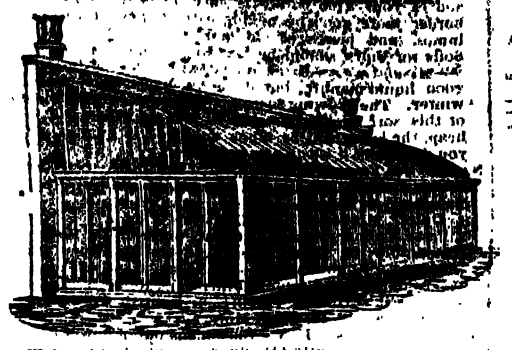
PROTECTION.—*W. C.*—You cannot have anything better than branches of the Spruce Fir as a protection against moderate frost for scarlet Geraniums in an open bed, or for tender climbing Roses, not growing on their own bottoms. The [illegible] equine covering pulled to pieces, or made thin the upper branches. For [illegible] this material answers well, provided there is enough of it. The branches should be packed over the plants in the form of a cone.

TRANSPLANTING.—*Countryman.*—The present is the best of all seasons for transplanting all kinds of hardy plants, let your advisers say what they like. Draw your border well, plant your Yuccas a little above the soil, steady them by some means, so that they cannot be blown about by wind, and remove them at once. That is what we have done, and should do again.

TUSSAC GRASS.—*B.*—We should sow the seed of this plant immediately, in damp peaty soil, in a greenhouse. It had better be sown *thickly*, and [illegible] encouraged to become strong before being planted out. If it is sown as thick as hay-seeds are, then it would be desirable to separate the plants which grow, and place them in separate pots, still keeping them [illegible] in a good greenhouse or well ventilated pit. It grows naturally in the peat bogs of the Falklands.

VINERIES.—*Susan.*—Plants do not do well on the back walls of Vineries. You may, however, try Camellias, the Cape Plumbago, and Scarlet Geraniums; and if you pull a brick out here and there near the roof, so as to form a nest for its seeds, you may get Mignonette in beauteous bush and to flower all the winter. Any light loose soil will do for Cacti; old mortar rubbish is a favourite of theirs. It rarely happens that plants can be named unless very common, if they are not in flower. Yours is apparently some Cape Mesbine; if you use it hot and plenty of light, without much water, it will bloom no doubt.

VINES.—*S. S.*—Royal Muscadine will ripen earlier than the Black Hamburgh and others you mention.‡



MISCELLANEOUS.—*J. A.*—We have no idea what ails your Yucca, which always flowers so late as to be cut with frost—unless the roots have got into a sunken soil in which case laying its roots dry would cure the evil. It is, no doubt, a local affection, the nature of which can hardly be judged of without actual inspection. In all probability the evil lies at the roots.—*M. B. G.*—We are sorry to be unable to assist you. An advertisement offers the only means we can suggest of obtaining the information you are in search of.—*A Reader.*—It is not common for a standard Magnolia to be in full blossom in the open ground at this season.‡—*A Subscriber.*—Thompson's Il Arcedo was published in 1812, and sold by Carpenter & Son, Bond-st.—*T. G. S. W.*—Edensor is situated at the gates of Chatsworth Park.—*A. Z.*—Most certainly raise your Vine roots, which are buried nearly 3 feet deep in clayey loam, as near the surface of the border as you dare. The Vines will do no good while the roots are so completely removed from the influence of heat and air.—*A Subscriber.*—Stephanotis floribundus cannot be expected to thrive in a cold pit, it is a stove plant; and should be kept during winter in a temperature of about 60°. Cut down the withering stems of your Erythrina Crista-galli, and by gradually withholding water allow the root to dry off. Place it where it will be free from frost, and keep it dry through the winter.—*Verax* &c.—The best and ultimately the cheapest fence for keeping rabbits out of a flower-garden is a wire one. It should be about 6 feet in height.

A dangerous enemy to [illegible] is the business of adventurers. The roots of Gentiana pneumonanthe may be readily, and divided in spring.—*W. D.*—The fruit of [illegible] is scarce at all [illegible]

The Scottish Thistle is only the common prickly variety of Cirsium arvense.‡—*W.*—Of the three specimens of plants which you sent, the [illegible] is the best. The [illegible] does not [illegible] plants more tender [illegible] one from another.‡—*R. H. R.*—The watering of your Camellias, which are growing in a low temperature, [illegible] freely three times a week, is the cause of their leaves turning yellow, and of the flower-buds dropping off. See that the pots are properly drained, water carefully, and place the plants in a temperature of about 50°, and they will possibly recover.‡—*A Novice.*—A good description of pit for growing Cucumbers, Melons, &c. is, when fermenting material is employed for heating, is the Rochford, a plan of which is given at p. 692, vol. 1843; but if hot water is used, a plan given at p. 803 of the present year may be consulted with advantage.‡

* As usual, many communications have been received too late, and others are unavoidably detained till the requisite inquiries can be made.

COTTAM AND HALLIDAY, ENGINEERS, FOUNDERS, &c., &c., No. [illegible] STREET, LONDON, and at [illegible]

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principle, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public or Private Buildings, &c., with Cottam's PATENT or ROGERS'S BOILERS. After 15 years' experience, and having fixed upwards of 2000 Apparatus for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale.

Materials may be had for those who wish to fix their own Apparatus.

THE TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

IRON HURDLES, best Wire for Strained Fencing, Ornamental Iron and Wire-work, Garden Chairs, &c., &c., and every description of Implement for AGRICULTURAL and HORTICULTURAL PURPOSES.

Show Rooms at their Manufactory, 2, Winsley-street, Oxford-street, where a large assortment of the above can be seen.

CONICAL BOILERS.—The Boilers invented by JOHN ROGERS, Esq., are made of several sizes, and may be obtained of JOHN SHERWIN, Ironmonger, Sevenoaks, Kent.

They may be seen in operation at Messrs. Chandler's, Vauxhall; Loddiges', Hackney; Henderson's, Pine-apple-place, Edgware-road; Rollisson's, Tooting; Pontey's, Plymouth; The Horticultural Society's Gardens, Chiswick; and in the Gardens of the Royal Botanical Society, Regent's-park.

The Agricultural Gazette.

SATURDAY, NOVEMBER 30, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.
WEDNESDAY, Dec. 4—Agricultural Society of England.
THURSDAY, Dec. 5—Agricultural Soc. of Ireland.
WEDNESDAY, Dec. 11—Agricultural Society of England.
THURSDAY, Dec. 12—Agricultural Soc. of Ireland.

As we informed a correspondent a few weeks ago, the general result of Mr. CAMPBELL'S PROCESS AND MATERIAL FOR STEEPING SEED, so far as we know it, has been unfavourable. The attention of our readers was called to this subject in an early Number of the *Gazette*, and there appears no necessity for qualifying or retracting any remarks that were then made. The season has been peculiar, and so severe upon all our crops, especially upon those sown in spring, that the results from such sources must, in great measure, be considered consequences of the weather—of Nature's rather than of the farmer's treatment. In spite, therefore, of the failure of this year's trials, we persist in recommending the subject as a fair one for experiment.

Though very probably original with Mr. Campbell, his process is by no means new, as indeed several correspondents have pointed out to us; and the practice which has been generally prevalent of steeping seed Wheat in urine or stale urine, may be considered evidence of this, for, though it be professedly for another purpose, it is doubtless beneficial also as impregnating the seed with fertilising material. This and the *à priori* probability that seed admits of being benefited in this way, combine to render the subject worthy of continued investigation.

Of course, no practical man believes that these steeps are to take the place of manures—they will always be necessary—all that we can suppose them capable of effecting is to give the plant a vigorous start in life; and, considering the numerous foes by which the *young* plant is surrounded, this is by no means unimportant.

The experiments we made on the subject this summer have utterly failed, variable circumstances at seed-time, and more especially the subsequent unequal and extreme ravages of game, have combined to render their results worthless. Their results have only been obtained within the last few weeks; and, had we not previously promised it, we should not now publish them—as, if taken unqualified, they are only calculated to mislead.

One thing must first be specified in Mr. Campbell's system of steeping seeds—we shall have a word or two to say about *it* presently—is in no way responsible for the following detail. It is not in the mere art of steeping seed; it is in the choice of the material to be used that the merit of the process lies. All manner of evil consequences may arise from want of judgment in this; but so long as none of them are attributable to the particular mixture put forth by Mr. Campbell, he, of course, cannot be considered responsible for them. We have no wish to bring up this gentleman's corn-steep, as, indeed, the only evidence we have of its composition—an analysis published in our columns some weeks ago—is by no means evidence in its favour; we only wish that where blame is due it should not be laid upon the wrong shoulders.

It may be remembered that we proposed steeping seed Wheat in eight different salts, viz., silicate, sulphate, nitrate, and phosphate of soda (*a*, *b*, *c*, and *d*, respectively), nitrate of potash (*e*), muriate, nitrate, and sulphate of ammonia (*f*, *g*, and *h*, respectively). This was done early in March; and after steeping in sufficiently strong solutions for about 50 hours, the several parcels were taken out, and on that and the following days they were sown (hoed in) at the rate of two bushels per acre, on plots of land each equal to a quarter of an acre, with intervening strips of half the size between each. When the process was commenced, it promised, as we thought, a continuance of fine weather, but the Corn had not been a day in the water before it began to snow, and the seed was thus put in the land under most unfavourable circumstances. In the course of three or four weeks, it became evident that lots *a* and *h* had been killed by the process; fresh parcels of Wheat were therefore steeped in silicate of soda and sulphate of ammonia, only for a shorter time than before, and the plots were re-sown, and they very soon exhibited a better appearance than any of the rest, and were evidently better also at harvest-time; but, owing to the irregularity just stated, they are of course excluded from the comparison which we have now to make.

In May, the whole field had a fair and blooming appearance, as we then stated to a correspondent, who mourned over the failure of similar experiments which *he* then had in progress; but rabbits and hares were at work, and all the upper part of the field was soon eaten off nearly bare.

It thus soon became evident that no dependence could be placed on results calculated from the *whole* of the field—that in fact the only parts of the plots which could be taken as at all representing the probable effect of the process were those at the lower end of the field, which would be cut off by a line across it, about 15 yards from the bottom. The plots were thus reduced from fourths and eighths, to pieces 1-20th and 1-40th of an acre. Notwithstanding the smallness of these patches, there is a singular uniformity in the amount of their produce. The following is a Tabular account of the quantity of grain threshed from each plot. It may be mentioned that the yield of straw appeared pretty uniform over the whole; there certainly was no such variety as to indicate the difference in the produce of grain.

Reference to steep.	Weight of grain in lbs.	Extent of plot in perches.	Weight of grain per acre in lbs.	Bushels per acre.
*	68	4	2720	42
b	65	8	1300	20
*	68	4	2720	42
a	74	8	1480	23
*	71	4	2840	44½
d	101	8	2020	31
*	70	4	2800	43¾
c	90	8	1740	27
*	69	4	2760	43
f	108	8	2120	33
*	76	4	3040	47
g	127	8	2540	39½
*	92	4	3280	51

* These are the unsteeped parcels.

From this it appears that the ammoniacal salts and the phosphate of soda are the best, or rather, to be in accordance with the figures, we should say, the least injurious of the steeps. These results certainly could not have been anticipated; it is difficult to account for them. The seed may have been steeped too long, and its vegetative powers may thus have become injured. Be this as it may, we shall not be deterred from repeating the experiment this year; but instead of trying each salt by itself, we shall use only two steeps—the one recommended by Professor Johnston, as published lately in the *Gazette*, and the other, sold by Mr. Campbell.

The experience of that gentleman this year, though probably better than our own, has certainly, if one may judge from his published circular, not been very favourable. The following are among the most encouraging testimonies he has received:—

"One is sown in Oxfordshire.—The soil, originally moorish, on a retentive bottom, having been for upwards of half a century under superior management, has now the appearance of a blackish loam, of moderate depth and consistency, with an admixture of old red sandstone chips and flints. Nine ridges, containing 2,3 Imperial acres, were sown with eight bushels of Barley, subjected to Campbell's Steep. Cost of the Steep 8*d*. Crop 10 quarters, weighing 52½ lbs. per bushel; and 1¼ quarter, weighing 50½ lbs. per bushel. Nine ridges contiguous to the former, containing 2.30 Imperial acres, were sown with 10 bushels of Barley, manured with 2 cwt. guano at 9*s*. Crop, 10¾ quarters, weighing 53¼ lbs. per bushel; and 1½ quarter, weighing 50½ lbs. per bushel. Sown in the last week of April; reaped 16th September.

COMPARATIVE RESULT PER IMPERIAL ACRE.

Campbell's Steep.						
Seed, 3.4 bushels at 8*d*.	£0	2	0			
Steep	0	0	8			
	£1	2	3			
Produce, 4.92 qrs. at 27*s*.	6	2	11	Return	£5	10	8
Guano.						
Seed, 4.2 bushels, at 3*s*. 6*d*.	£0	15	1			
Manure, 1.8 cwt. at 9*s*.	0	15	6			
	£1	10	7			
Produce, 5.14 quarters at 27*s*.	6	19	11	Return	5	9	4
Diff. in favour of Campbell's Steep per acre,					£0	1	4

—*James Sime, Land. Surveyor, Murrayguie.*

Before we can admit the accuracy of this balance of the accounts, we must know if any of the guano that was applied remained in the land, as it is very probable some did, after harvest. If so, no credit is here given for it.

The following is a very decided statement in favour of the steep—though we rarely like to attach much value to mere estimates or "guesses."

—— "with the Salt-steep the crop was good, upon bad land, at a guess *four times more than where nothing was used*. There was a saving of a bushel of seed per acre. It was sown in a field where salt, guano, nitrate of soda, and nothing had been applied. All ripened equally, and were cut together. . ."—*James Hunter, Auchterarder House.*

Besides these, a variety of communications are published, most of them indifferent; some absolutely conclusive against the *system*; and, as we said before, if these are the best testimonies Mr. Campbell can produce, we fear general experience this year is against him.

The season, however, has been exceedingly unfavourable, and we hope some of our readers will join us in giving the process another year's trial.

AN EXPERIMENT ON POTATOES.

By JOHN GREY, Esq., of DILSTON.

ALTHOUGH the instances of failures in the Potato crop in this district are fewer, and to much less extent this year, than in many former seasons, a detail of an experiment which I have now proved, showing the comparative produce of autumn and spring-planted Potatoes, both of which were very full crops on the ground, may throw some light on the subject, and at all events shew that the fear of the plants being destroyed by frosts in the winter, on tolerably dry land—and no one should plant Potatoes on any other—is groundless.

Immediately after the harvest in 1843, I had a piece of Oat stubble turned up with three horses in a plough, as deep as the soil would admit of. The land was a damp loam, on a retentive subsoil, that had been thoroughdrained the previous year; it was then ploughed across, and made up into drill-rows of the width of 30 inches. About the 20th October, when the Potatoes of that year were taken up, it was planted, partly with small Potatoes whole, and partly with large ones cut in two, having had a moderate quantity of dung, but slightly fermented, applied to it; the drill-rows were then ploughed up pretty deep, so as to give the plants a good cover. In the latter end of April, 1844, a harrow was run along the rows, to break the crust and admit the air, as well as to give an opportunity of picking off any couch or roots that might be turned up. Very soon after this operation, the shoots of the young crop appeared in great vigour, to the surprise of some of my good neighbours, who thought that I was adopting a very heterodox practice. The land underwent the usual course of hand-hoeing and scuffling, until the time came when, the tops being tolerably large, it was necessary that the rows should be earthed up. Before doing so, I had 1 cwt. per acre of guano sown broadcast over them, which the plough immediately following, turned up against the plants. I did this on the ground that the tubers which are thrown out laterally from the stem require more support to bring them to perfection, than they can derive from the manure which is placed in the hollow centre of the drills. The crop went on with a promising appearance throughout, but did not exhibit any unusual bulk of tops. On each side of this plot, a piece of ground was worked and planted with Potatoes in the end of April, in rows of the same width, and receiving in every respect the same treatment, except that the dung having lain longer in a heap, and become more compressed, must have been applied in rather a larger proportion. The plants in this case consisted entirely of large Potatoes cut in two; and the same application of guano was given to them as to the others. In these plots no failure occurred; the ground was well covered, and the tops were more luxuriant than in the autumn-planted plots, so that it seemed very doubtful which of the two would in the end be the most productive. The tops of the autumn-planted ones fell, indicating ripeness, a fortnight before the others, and were taken up in the beginning of October. The produce of each plot were carefully taken up with the graip, or three-pronged fork, and put into sacks, so that no mixture could take place, and afterwards a row in the middle of each plot, so as to come to a

correct average; the stalks were then weighed, and the result was as follows:—

The autumn planting with cut Potatoes yields at the rate of [illegible] pounds per square rod.
Ditto with large Potatoes, cut in two [illegible] 29.
Spring planting with cut Potatoes [illegible] 30.

The kind of Potatoes on which this experiment was tried, is that known in these parts by the name of Hunt's-west. The quality is good in all the plots, but the autumn-planted, if anything, rather more mealy.

I am repeating the experiment this year, and have planted, a fortnight ago, some whole Potatoes, and some cut in two; but in the former, I have this time kept out the very small ones, and planted only those of a medium size, whole; for it seemed to me last year that those of them had been planted of too small a size, which caused them to put out too many shoots, and with inadequate vigour. Another experiment may, perhaps, vary the comparative produce, and tend to establish the point of preference between autumn and spring-planting. As no failure took place in any of these plots, we have no right to presume, from this experiment, that autumn-planting will prove an antidote to that growing calamity; but as far as my observation goes, I am strongly inclined to think that it affords a security against it, and that the principal causes of failure are to be traced to injury sustained by the seed, from being improperly kept through the winter, and its vegetative power being frequently exhausted by shoots that have been made before planting in the spring, as well as by the planting being deferred till the ground, under the process of working, has been too much deprived of its moisture. Against these causes of failure the autumn-planting is a security: and if the result of future experiments should bear out that which I have now detailed, the advantage of planting in autumn will, I think, be fully established. It has been stated as an objection to autumn-planting, that time is not allowed for cleaning the land sufficiently, so as to make it fit for sowing to Grass with the ensuing Corn crop; but I should call it bad farming to have land so foul after one crop of Corn, as to present that difficulty. Besides which, as autumn-planted Potatoes are generally ready to be taken up in the beginning of October, a considerable time is available for preparing the land, either for receiving winter Wheat, or spring Corn. Independent of which, it is possible so to arrange it as to have the Potato crop succeeded in the following year by one of Swedish, or other Turnips; and thus affording the fullest opportunity of sowing the land to Grass in the best possible condition.—*John Grey, Dilston House, Oct. 24, 1844.* [See a Leading Article in another part of this Paper.]

THE PLOUGH.

(*Continued from page 797.*)

Before drawing the inference as to the proper form of the mould-board from what we have thus shown to be the proper position of the turf, I may as well first say, that the amount of surface exposed depends wholly on the relation between the dimensions of the furrow-slice, and not in the least upon its actual dimensions. The surface exposed will be a maximum, if the sods be cut rectangular, and if the proportion between their depth and breadth be that of about 7 to 10; and if these two conditions be observed, then the amount of surface exposed will be constant, it will not vary, however the actual depth or the actual breadth of the sod be altered. The same surface is exposed in a double as in a single roof, the span and the slope being in either case the same.

There is one other point regarding the proper mode of ploughing, still to mention. It is not always the object of the farmer to expose the greatest surface of ground that he can to the action of the air. His aim is sometimes merely to sever, and that in a very shallow way, manure or other matter laid on the surface of the land. This will, of course, be most perfectly effected, the flatter that the sods are made to lie the shallower, and the wider they are cut. And here it may be well to say a word or two regarding the economy of having your implement to do exactly what you want done, though it should be at the expense of additional force.

In ordinary farm work there is every possible variety, arising from the various nature of weather and of soil; and, possibly, economy would advise the farmer to have two or more mould-boards, of forms varying so as to suit two or more cases in which the difference is extreme, these mould-boards being all attachable to the same framework; but it must always be borne in mind that nothing is so economical as simplicity, and that there cannot in Great Britain be circumstances so different as to justify the Berkshire farmer in retaining his clumsy implement, with its clumsier appendages of [illegible] &c., or the Kentish farmers in retaining their cumbrous thing form of the turf-wrest plough, while all over the varying climates and soils of Scotland there is but one form of plough used, or at least ploughs varying nothing in principle, and but little in details. All this is necessary to be true; and yet the truth of the general proposition, that economy tries to get its work well done, though it be at additional expense, is undeniable; and I shall have immediate occasion to apply it. It will not do to have mould-boards varying in form so as to save every little difference of circumstance; and this is the less necessary, because, as we have seen, the position of the sod is dependent, not so much on the form of the mould-board on its own form—the relation between its breadth and its depth—and thus the farmer can get his manure covered perfectly well by a thin covering of earth, whatever be the form of his plough. Notwithstanding this, the circumstance of the position of the sod being dependent on the form of the sod, and not on that of the mould-board, is not to induce us to leave the furrow-slice to find its own position. We must have such implement such that the sod will not merely fall on the mould-board into its ultimate position, but that it will be pushed into its proper place. This is more necessary in ploughing lea land, where, by a mould-board of a given form, the upper edge of the sod may be pressed in so as entirely to bury the grassy surface. It is also well in [illegible] because, if the land be in a proper state for [illegible] it will tend to break the sod, and so facilitate the [illegible] action of the harrow, &c.

We have thus seen that the best mode of ploughing for general purposes is when the furrow-slice is cut [illegible] regularly, and of such dimensions that it shall be at an angle of 45°. It is a question which, perhaps, chiefly affects the draught of the plough, but certainly also, in some measure, its performance, that the turf shall be cut perfectly by the coulter and share, that there may be no tearing when it is moved by the mould-board; and it is also a point affecting the draught as much as the performance of the implement, that there be no lateral thrust tending to push the turf bodily aside. This will only increase the draught of the plough, and tend to spoil its work. The form of the implement, then, so far as the nature of its work is considered, must be this:—The coulter and sock must be so far before the mould-board, and their position with regard to each other must be such that the sod be cut of a rectangular form, and that it be perfectly cut before the moving part of the implement come to act upon it. The mould-board should be such that the line where it touches the ground may be a straight line, corresponding in direction and position with the corner about which the turf turns, and that the commencement of its curved surface may be a straight horizontal line, where it joins on to the share, while its termination is a straight line hanging over on the other side of the perpendicular, at an angle of 45°. The curve between these two lines must be as uniform as possible, in order that the turf may be twisted gradually, not abruptly. The length of the mould-board must be such, that the angle its surface forms with the turf as it passes over it, may be such, that when the implement is working on a loose soil, that soil may slide over its surface and be laid aside rather than be pushed before it. The mould-board and the plough generally should be fitted for an extreme case, and then it will be sure to be fitted for all ordinary cases, though it may then work under a disadvantage. The angle, then, which the surface of the mould-board makes with a line at right angles with that in which the implement moves, must never be less than the angle of repose of soil on iron.* It is evident that a great number of curves may be drawn, each possessing all the properties which are here required of a mould-board, that it may work well; we now have to consider what is to guide us in choosing from among these the one which works easiest.—*M. S.*

* The angle of repose of one substance on another, is the angle at which the surface of the latter is inclined when the former just ceases to slide over it.

REMARKS ON CHALKING.

Having read your remarks on the subject in a late *Gazette*, and asking, as you do, for further particulars on this subject, allow me to offer a few observations on the mode adopted in this neighbourhood, where it has been carried on to a very considerable extent for many years past, and with the most beneficial effects, on the strong clayey loams as well as all other descriptions of "sour red land" in this vicinity. The plan for raising the chalk is the same here as is practised in Hertfordshire; there is, however, a very material difference in the cost, a much larger quantity being here spread per acre for a much less sum than is given in your account; and this, in my opinion, is to be attributed to our having no "middleman" between the farmer and workmen: generally, one of the best labourers is selected as foreman, who shares with the others in the work, but with the understanding that his wages are to be 1*s.* per week above the others; in many cases, also, he takes the job himself, employing the rest on his own responsibility. Our method, also, of sinking pits is precisely the same as mentioned by you; but now comes the difference: here it is paid for by the acre, and at so many bushels per pole, which being never less than 18, makes 2880 bushels per acre, and the price from 35*s.* to 40*s.*, generally 38*s.*, including the filling in of pits, &c. The buckets in common use contain 1½ bushels each, and the chalk is wheeled away at once into heaps, making about 1920 to the acre; if, then, these heaps are at the beginning placed in two lines, at right angles, and at a distance of about 8 feet in one direction, and 5 feet in the other, they will have the appearance of the annexed diagram on the ground. A very simple plan of ascertaining that the full quantity is deposited on the ground is [illegible] thus obtained, as by a very casual observation before spreading, it will be seen whether the heaps are kept in their proper rows, and at regular distance. The advantages of chalking are now so fully appreciated by all farmers in this neighbourhood, that but few, if any, having lands of the description above mentioned, but what are availing themselves of it where it can be procured, and it is generally to be met with at a depth of from 7 to 10 feet: in cases, however, where it cannot be [illegible] obtained, many go to the nearest chalk pits and employ their horses in frosty weather and at other times when convenient. As regards the [illegible] of the chalk, this is beyond me; there is, however, a somewhat significant term in use amongst the workmen, that the more "soapy" the chalk, the better it is, being more speedily pulverised by the frost, and it is generally found to be more "soapy" the greater the depth. The fields most commonly selected for chalking are old fields in course for Wheat, and sometimes Wheat stubble, in preparation for the ensuing crop. In addition to the great good effected on the land, another weighty reason is in the employment it affords to the numerous unemployed poor who are to be found in most parishes at this season of the year; and as an inducement to their exertion, several of the large landowners in this county have most handsomely contributed, for several successive years, in some cases one-third, and in a few instances one-half, of the cost per acre.—*F. M. C., Savenake Forest, Marlborough.*

[Can you forward us a specimen of your best chalk?—Ed. with notice.]

SKETCHES OF EAST LOTHIAN HUSBANDRY.

Rotations of Crops.—The general adoption of alternate husbandry has been already mentioned as one of the peculiar features of East Lothian Agriculture; although, generally speaking, every farmer in this county is prevented by express covenants in his lease from growing, upon the same piece of land, two white or exhausting crops in succession, without an intervening green or restorative one, yet none of them is restricted to any specified rotation of cropping. The choice of a judicious course being mainly regulated and determined by the quality of the soil and the local circumstances of particular farms, is very properly left to the judgment and discretion of the tenant himself. The proprietor, therefore, lays down no special rotation of crops or system of cultivation for the guidance or observance of the farmer; the only period during which he interferes with the mode of management—provided two white or corn crops are not taken in succession—is the last four or five years of the lease. No obligatory covenants, however, are requisite to enforce the observance of alternate husbandry in East Lothian, except perhaps towards the close of a lease whose renewal is not expected or desired. The farmers follow certain courses of cropping suited to the soil and circumstances of their respective farms, from a conviction that it is advantageous for themselves to do so; that is, from a regard to their own interest.

Although a rotation of some kind or other is generally adhered to on every farm, yet particular circumstances frequently render slight deviations from the regular course expedient. Some farmers, for instance, often take Potatoes after Grass, and Turnips after Potatoes—both evident violations of the principles of alternate husbandry. Sometimes, also, when a Grass field, in consequence of a failure of the Clover or some other cause, does not afford or promise a good pasturing, it is ploughed up for Oats after the first year, although, according to the rotation pursued, the field may properly require to lie two years in Grass. To rectify this deviation, and to equalise as far as possible the quantities of the different crops annually grown on the farm, some one of the other Grass fields included in the same course is allowed to remain in pasture a year longer than the usual period. Slight deviations of this kind are of general occurrence in the best managed farms.

Upon the strong clay soils, of which the greater part of the county consists, the rotation pursued and the crops cultivated are nearly similar. The following is the most general course of cropping throughout the county on adhesive soils:—

1st year	Fallow, dunged.
2d "	Wheat, with Clover and Rye-grass seeds
3d "	Grass for Hay, soiling, or pasture
4th "	Oats
5th "	Beans, dunged
6th "	Wheat.

After which the fallow is repeated and the rotation recommences again.

As remarked in my last paper, the extension of furrow-draining, by rendering the soil more easily pulverised and cleared of root-weeds, has obviated to a great extent the necessity for resorting to a bare fallow, even upon stiff, adhesive clays. Swedish Turnips are now, therefore, not unfrequently substituted, and begin the rotation, instead of fallow. The above course, which has been found peculiarly adapted to the soil of the greater part of this county, is sometimes modified and extended by allowing the land to remain two years in Grass instead of one. The Grass, in the latter case, is either cut for hay or soiling the first year, and depastured the second, or it is depastured both years. When the crop happens to be good, it is generally mown the first year, partly for hay, and partly for soiling the working horses in the stables, and the fattening cattle in yards, as previously adverted to.

Upon the light and medium descriptions of land, suited to Turnip husbanding, the following rotation is that usually followed:—1st year, Turnips; 2nd, Barley, Oats, or spring Wheat; 3d, Grass, generally depastured; 4th, Pasture; 5th, Oats. Upon this kind of land the Turnips, or a certain portion of them, are eaten on the ground by sheep. The Grass break is also frequently extended to three years, as this quality of land is not calculated to undergo as close and severe cropping as that of a stiffer and more adhesive character. I may here observe, that upon very strong retentive clays it is considered injudicious and inappropriate to allow the land to remain in Grass for a longer period than one year, or two at the farthest. The foregoing rotations are those in general practice throughout the low and middle parts of the county. In the upland district Wheat is but rarely grown, and bare fallows are never resorted to. Turnips invariably begin the rotation, followed with Barley or Oats, and several years of Grass. I should observe that as the nature and texture of the soil of large farms are often very different,

two rotations are not unfrequently pursued on the same farm, each adapted to the particular soils. Upon the dry, loamy, and fertile district of Dunbar, the following course of cropping, somewhat different from the rotations already enumerated, is that usually adopted, viz.:—1. Turnips, dunged, and generally eaten off; 2. Wheat, with Clover and Rye-grass seeds; 3. Grass, fed off with cattle or sheep; 4. Oats (usually the red Potato variety); 5. Beans, drilled and horse-hoed. Instead of Oats, Wheat is often taken the fourth year, which confines the rotation to four crops.

The following interesting and valuable observations in reference to this rotation of crops, and to illustrate husbandry in general, are extracted from the "Statistical Account of the parish of Dunbar," written by the Rev. J. Jafrey, its present minister, who is a zealous practical agriculturist, and published in the "New Statistical Account of Scotland":—"This course (speaking of the above), peculiar to the parish, has been called the Dunbar system; but objections have been made to it. Wheat, every second year, it is said, exhausts the soil; the answer is, that the food of plants in the soil may be exhausted by one crop, while the soil itself cannot be exhausted. Where there is a command of manure there is no system which will so richly repay the labours of the husbandman. It was adopted here for many years on one of the best farms, without any diminution of either quantity or quality; and in order to ascertain whether soil is injured by frequent crops of Wheat, the glebe of Dunbar was properly dressed, either with sea-weed, street-dung, or soot, and cropped with Wheat for five successive years. The result was an extra crop every year, and the land left in a condition that it may produce a crop or two of any kind without additional manure. The least crop in the succession was on the third year 10½ bolls (5¼ quarters) per acre; it promised to be the greatest, but it was lodged flat as the surface soon after it came into ear. All the other crops were above 12 bolls (6 quarters) per acre. One season, exactly suited to the soil, there were 8¼ quarters per acre; and the last of the five years there were 7 quarters per acre. It was ascertained that on each of three of these years there were more than 300 stones of straw per acre. The soil is a sandy loam. There is another field in the parish which has produced Oats four successive years with increasing produce and fertility. Hence it seems to follow that land, properly cultivated and manured, may produce abundantly the same kind of crop in regular succession. If the food of plants is exhausted in exact proportion to the weight of crop produced, it is worthy of investigation, whether the advantage of changing the kind of crop arises not from one kind giving off food for another, but solely from the different modes of cultivation which different kinds of crop admit of at different seasons."—*T. Sullivan.*

ON MINERAL AND INORGANIC MANURES.

No. XXIX.

By Professor Charles Sprengel.

(Continued from page 730.)

d. Turf-Ashes.—The long sward of barren meadows or other waste land is cut off in thin slices, which being divided into smaller pieces, and placed against each other, are left to dry, then placed in heaps, lighted, and the obtained ashes are then strewed about, ploughed under, and the soil thus further prepared.

A soil manured with turf-ashes will always yield better crops than one manured with peat-ashes, which is caused partly by the great amount of ashes brought on the same area of land, and partly by containing a greater amount of manuring mineral substances. They are also preferable on account of always containing potash, combined at times with carbonic acid. Turf-ashes, however, like wood and peat ashes, have not always the same value. This is determined both by the nature of the sward and the quality of the earth which it covers. Grass often consists of Mosses and a felt of roots belonging to bad, barren plants; and if the earth adhering to these is also bad, the ashes which will result from the burning of such turf will have but slight manuring powers, as they will then merely contain the less powerful mineral manures—lime, potash, common salt, phosphate of lime, gypsum, &c. In this case, quantity may somewhat supply quality, the turf being cut a little thicker, for the sake of obtaining more ashes, which, however, will at times be impracticable, the stratum of humus below the Grass being very thin. For the sake of knowing before-hand what result the manuring with turf-ashes will yield, and to see what advantage may arise from burning our turf, it is very advisable to subject the ashes of the turf to a previous chemical analysis. The following are some of the results of my analyses of turf-ashes.

1. Ashes of turf 1 inch thick, which were derived from a moor covered mostly with Reed-rushes. 100,000 parts consisted of—

97,574	parts	of silica and quartz sand
0,065	,,	alumina
1,200	,,	oxide and protoxide of iron
0,520	,,	oxide of manganese
0,360	,,	gypsum
0,203	,,	magnesia, partly combined with silica, partly with phosphoric acid
0,039	,,	potash combined with sulphuric acid and silica
0,040	,,	soda combined with silica
0,099	,,	phosphate of lime and a little phosphate of iron
0,030	,,	common salt

100,000 parts.

This analysis proves that these ashes will not produce any fertilizing effect, even if 20,000 lbs. were to be used on the Magdeburg acre of land, because by this quantity the soil would merely receive 20 lbs. potash, 4 lbs. common salt, 102 lbs. sulphuric acid, 37 lbs. phosphoric acid, 54 lbs. magnesia, 161 lbs. lime, 100 lbs. alumina, and 16,715 lbs. silica; so that the burning of the sward, soil, whence the ashes are derived, could only have a beneficial result if conjointly a manure of wood-ashes, or such mineral substances (marl) were to be added, as are rich in phosphoric acid, magnesia, potash, common salt, and lime.

2. Ashes of a turf one inch thick, derived from a good soil rich in humus, which were overgrown with Reeds, Rushes, much Moss, and a little peat. 100,000 parts consisted of—

97,434	parts	of silica and quartz sand
0,065	,,	alumina
1,200	,,	oxide and protoxide of iron
0,520	,,	oxide of manganese
0,360	,,	gypsum
0,203	,,	magnesia partly combined with silica
0,039	,,	potash combined with sulphuric acid and silica
0,040	,,	soda combined with silica
0,099	,,	phosphate of lime and a little phosphate of iron
0,030	,,	common salt

100,000 parts.

If 100,000 lbs. of these ashes be placed on one acre of land (which will be the case if the Grass burnt be one inch thick), the soil will receive thereby 360 lbs. gypsum, 203 lbs. magnesia, 39 lbs. sulphate of potash, 40 lbs. soda, 99 lbs. phosphate of lime, 30 lbs. common salt, &c. From this it is seen, that if these ashes are to be beneficial, the soil must, in addition, be manured with lime, bone-dust (phosphate of lime), common salt, and potash, all which are to be found in wood-ashes, or good kinds of marl.

In England, the land off which the turf has been burnt is mostly as well manured with lime, which, certainly, in cases where the Grass-ashes are so deficient in lime, as those last mentioned, will be very beneficial, as the lime will decompose the carbonic humus and the organic remains of the soil, and thus procure more vegetable food for the plants.

3. Ashes of a turf 1½ inch thick, of a sandy loam, rich in humus, which was overgrown with Reeds, Moss, white Clover, and some good Grasses and herbs. 100,000 lbs. consisted of—

93,071	parts	of silica and quartz sand
1,352	,,	alumina
1,728	,,	oxide and protoxide of iron
0,320	,,	oxide of manganese
0,619	,,	lime
0,327	,,	magnesia
0,380	,,	potash combined with sulphuric acid
0,079	,,	common salt
1,706	,,	sulphuric acid combined with potash and lime
0,448	,,	phosphoric acid combined with lime and magnesia

100,000 parts.

These latter ashes are evidently preferable to the two former, as they contain more potash, phosphoric and sulphuric acid, common salt, and magnesia; and as they are also not deficient in lime, it is to be supposed that if only 50,000 lbs. were used per acre, they would act beneficially. But as they do not (like the preceding sorts), possess either caustic lime or its carbonate, a simultaneous manure of burnt lime would be very beneficial.

Turf-ashes, however, do not manure only by means of the substances they contain, but also by one which is formed in them, and this is ammonia, which is generated by the protoxides of the ashes being converted into peroxide at the expense of the water. I have dilated on this process under the head of Burnt Clay, to which I refer the reader. It is obvious that the more protoxide of iron there is in the ashes the more ammonia will be formed. It is also well to be attended to during the burning of turf, that all the protoxide of iron be converted into an oxide, which will be best effected if the turf be burnt in small heaps, slowly and at a very gentle heat, hindering them from bursting into flames. And that the ammonia thus formed may not escape, but, on the contrary, be fixed by the humic acid of the soil, the ashes, after having been spread, should be ploughed under as soon as possible, but very shallow, as the access of the nitrogen of the air is indispensable for the forming of ammonia. The formation also of caustic lime in the process of burning turf will act as a safeguard on the carbonic humus and the organic matters in the soil, kill the vermin, and be useful in many other respects, as I have shown in my work on Cultivation.

Home Correspondence.

Cotswold Farming.—The system of cropping upon the Cotswolds was, some years back, Wheat upon two or three years' lands, which was generally breast-ploughed and burnt; then, Oats, and Turnips, which had all the manure which was made upon the farm; the rest of the land was left in a sort of fallow, for without any manure the Turnips were very bad; the whole was in a manner folded in winter, and then laid down with Clover and Rye-grass, in either Barley or Oats. I am sorry to say many farmers still follow this course, though all now drill ashes, and most of them bones with the ashes, on the land which has no manure for Turnips. The more enlightened farmers in our district have discontinued sowing Oats after Wheat, and keep some of their land in a five years' course, and some still in a six years' course, by putting Vetches or Peas after the Wheat crop. In writing upon Cotswold farming, I must be impartial, and acknowledge that there is very little clean farming. I will allow that our land is very natural for Grass, and it is very difficult to keep it clean of couch Grass. This evil is never more visible than in the Wheat crop, and many farmers actually justify it, upon the principle that it ameliorates the land; and, if you attempt to clean the land for Wheat, you make it so light that the crop is destroyed by the rise-worm, forgetting that this evil is soon remedied by Crosskill's clod-crusher, or any heavy roller. The effect of breast-ploughing and burning in this neighbourhood is almost magical, not only on the Wheat crop, but in the after crops. It is the fashion to write against it, and many landlords are discontinuing it upon their estates. It appears to me the principle upon which it acts here is entirely misunderstood; Mr. Minchin has written some good things upon it in "Baxter's Agriculture;" but he has evidently mistaken the principle here, for he says it does not answer so well upon sands. Now, the down lands are the dead earthy lands I spoke of in my last letter, upon which paring and burning answers remarkably well, and this soil is almost entirely composed of sand. I believe Mr. Minchin is right as regards most countries; but not as regards our hills. It is generally believed the gypsum of the Ash is the cause of its fertility; I think otherwise. A few years ago I accidentally met Dr. Buckland and Dr. Daubeny, upon a coach going to Oxford: I was not acquainted with them, but knowing who they were, we talked much of farming. I told Dr. Daubeny paring and burning did wonders upon our land, and asked him how it acted; after some pause, he seemed to think the gypsum acted beneficially; I own I was not satisfied. Some time after I attempted to analyse some of this earthy land, expecting—why, I know not—to find a good deal of alkali in the soil; but, to my astonishment, found *none*. From information subsequently given by Dr. Daubeny, it struck me, that connected with this was the principle of the good effects of paring and burning. Our oolite stone will not effervesce with acids, yet, the acid being thrown off by the action of fire, it makes excellent lime; so the burning throws off the acid from the soil, and though it destroys some vegetable matter, it endows it with alkaline properties, without which the remaining vegetable matter in the soil could not be decomposed (?) I believe this is the reason why burning answers so well here; and, if I am right, burning would be injurious where there already exists sufficient alkali in the soil to decompose the vegetable matter.—*T. Beale Browne, Salperton.*

Hedges.—It is too often the case that we see hedges long neglected assuming such a height and breadth, that they are neither useful nor ornamental; and many being allowed to get too high, grow open at the bottom, and thus decay and die. Except for particular purposes, farm-hedges should not be allowed to get to the height they frequently are allowed to grow to; for in our north country, where we have such heavy snow-storms, that block up roads, they shelter so much drifted snow, that the hedges, by being too high, are bent down, and often broken and much damaged; whereas, if they had been kept lower, they would have been closer and more compact, and would generally escape unhurt by the snow; likewise they are more ornamental, and it is much easier to get them pruned. In a late Number of the *Chronicle*, one of your correspondents condemns the existence of hedges on farms altogether. No doubt he may be right to some extent, where the inclosures are small, and detrimental to a free circulation of air for drying the corn in harvest; but this is not the case where the fields are of considerable extent—say from 10 to 20 acres, or more. Hedges are often of much service in a tempest, or on exposed situations, as they give shelter to cattle, &c., when they would otherwise be unable to stand out to graze; besides, they add very much to the beauty of a farm or district. But to the subject of improving Thornhedges. Where they are got too open and straggling, I would advise, not that they should be cut in at the side-branches, almost to the main stem of the plant, as is sometimes done; but to give it the radical cure at once, by cutting the hedge completely to within 10 or 12 inches of the ground, trimming off all the side-branches close to the stem, leaving nothing but the bare stumps. This should be done in the winter season; when this is done, dress the hedge-border on both sides, if in need of it, and it will be got quite easily at to clear it of weeds; by the month of May, the plants will push a great number of fine young shoots through the bark of the old stems; and by the end of autumn the hedge will average 2 or 3 feet high or more, assuming the appearance of a young Thorn-hedge of 3 or 4 years' standing. In the autumn, give it a prune on both sides, to take off the straggling side-shoots, and give it a tapering shape to the top, making the top of an equal height: thus you will have a better hedge than ever it was before in the course of three or four years. Of course, where the hedge is not protected by a stone built dyke, it will require protection by palings for two or three years, as cattle would crop the young shoots, and otherwise damage it.—*A. W., Mirefield, Yorkshire.*

Campbell's Steeps.—I some time since promised to give you the results of some experiments with steeps. Last spring my self tried Campbell's 6, with spring Wheat, which was a failure; attributable, as I then thought, to the continued drought. On Oats he was more successful; they came up evenly, retained a good

colour throughout their growth, and have yielded comparatively well. The experiment on Wheat has been resumed under my own eye, and running strictly with the printed directions, accompanying them. Part of a field was sown early in October with Wheat so prepared, which has to a great extent germinated on the ground; the seed for another portion of the same field was at the same time, and after the prepared one had dried (by mistake) with lime; this all grew, as did that of another portion dried with ashes. Mr. Campbell might say that the steep was too strong (though his own directions were followed), certain it is that the lime, by throwing off the ammonia, of which it is principally composed, had neutralised its effects on the second portion; but why should the part treated with gypsum vegetate better than the first? I have tried a variety of steeps, but find nothing to answer so well as the undiluted urine from the manure tank. This appeared at first by its powerful stimulant, and to test it, I soaked 40 grains of Wheat (in August) for 50 hours, which were sown at the same time and place with 20 others unprepared. The steeped seed came up some days before the other, soon outstripped it in growth, and has in every respect taken the lead since; I have, in consequence, soaked all my seed Wheat, excepting that prepared with Campbell's steep, to be similarly pickled, and nothing can surpass its present appearance. Whatever the ultimate effects may be, there can be no doubt of its proving at least equally efficacious as the common saline preparation in guarding smut, while it certainly promotes the early growth of the plant, causing it to tiller exceedingly well.

Useless Animals.—The number of these kept in this country is immense, and the sums paid for their maintenance absolutely incredible. I wish to call the attention of the public to this evil, which I believe to be a sin of the first magnitude, and an abuse of the trust conferred upon us by an all-bountiful Creator, as the food consumed by them is so much indirectly taken from the poor, by very much enhancing the price of the remaining portion of the provision of the people. Let every one who keeps a useless animal reflect that he is wasting the resources of the country, and with a teeming population bordering on starvation, the money thus spent on pampered animals would cause employment, fill the mouths of thousands, greatly improve the land, ameliorate the condition of human beings, and benefit the nation.—*S.*

Drilling Wheat.—It is surprising to see with what alacrity the farmers of our village have taken up the dibbling system, there is not a single allotment where Wheat is not dibbled; men, women, and children, have been hard at work for the last month. The great fault is, too little room—four inches between the rows, and four inches apart in the rows, seven, eight, and nine grains in each hole. This is the distance, I believe, in every case but one, I saw a labourer dibbling the other day, which was the same distance in the row, but eight inches between the drills. I tried to convince him that two grains were enough all the holes. He replied he should not like to have a piece set with four or five in a hole, but I hope in time to see this prejudice removed. I plant, myself, with Mr. Campbell's machine, at 6 inches distance, and I think another advantage is, that two crops in succession may be obtained off the same piece of ground, by planting between the rows of the previous year.—*Sandford.*

Correspondence.

Some time ago, I read an article in your last Number, signed "J. Dodson," complaining of the wet state of his meadows, and of the weed which he calls Reed-heads, a plant which I do not know, by that name, but suppose it to be a species of Common or Flag, whatever the plant may be, of the more difficult to eradicate. I could not suggest a better remedy than he himself proposes, namely, thoroughly tile-draining, severely scarifying, and sowing with fresh clean seeds of the proper permanent pasture grasses. To carry off the surface-waters (which he recommends to be done, instead of bush-drains, open and quite clear), would be kept clear will, I have no doubt, with the aid of the tile-drains below, effect a very great improvement in the appearance of his meadows.—*Rev. T. Cockburn.*

Agricultural Literature.—An Extract from "The Gentleman Farmer, &c." published by Oliver and Boyd, Edinburgh, in 1806. [illegible] that the chemistry, as applicable to agriculture, is not the [illegible] the present day only [illegible] the former it is not necessary that a gentleman [illegible] chemist. There are [illegible] principles relative to agriculture [illegible] ought to be ignorant of. [illegible] cessary shall be here stated; beginning with [illegible] attraction and repulsion, which [illegible] the science of agriculture [illegible] Page 319—After [illegible] is laid down above, [illegible] between the smallest [illegible] in agriculture, which [illegible] stone of the fabric [illegible] is, the more water it will hold [illegible] the weather a century ago [illegible] Oats that grew in a warm [illegible] 10 days earlier than Oats that grew in cold [illegible]

Semper ego auditor tantum.

Prodigious Potatoes.—Mr. Worthington, farmer, Hinkin, has dug up several large Potatoes, varying in weight from 4½ to 5 lbs. each. In this neighbourhood they are not only large, but rise well where they have not failed in coming up; and it appears to me that where they have failed, it is owing to the state of the ground, the manure being too dry, and to the state of the atmosphere at the time of planting, and not so much to the Potatoes as is supposed; and as a proof of this I took home a heap of Potatoes, which had been heated and thrown away as worthless, and planted all of them in June in the garden, with manure, and almost the whole came up and produced a fair crop; and the whole of the last season [illegible] were [illegible] of the [illegible]

Societies.

AGRICULTURAL IMPROVEMENT SOCIETY OF IRELAND.

Council Meeting, Thursday, November 7, 1844.—The following is a portion of a letter received from the Marquis of Downshire:—"The intention of establishing in London a Chemistry College, has suggested to me that it might be very beneficial to the farming interest in Ireland, if the Society would elect one or more experienced chemists in the chief towns in Ireland, not with salaries, but merely appointing one or more in each town, and arranging with them a scale of charges, for analysing manures, earths, minerals, or what not, to be hung up in the shop, to be referred to on the application of the persons requiring information. Such a system would gradually bring chemistry and the necessity of more accuracy in the management of the soil, and of the suitable crops to be grown on it, into notice, and pave the way for an Irish College of Chemists, after experience has been had of that which is about to be tried in London.—The report of the sub-committee for preparing the list of premiums for the cattle-show at Ballinasloe, next year, was then submitted to the council, which suggested many important alterations from the premium-sheet of the present year, and, among the rest, that all local competition should be abolished; and that all the different breeds of stock, both males and females, should compete in separate classes; that the premiums for South Down sheep and for swine should be increased considerably; that the sum usually allocated for agricultural improvements should be increased to 100*l.*, and the prizes for butter and wool be continued, and for poultry also increased; that the sum of money usually allocated for extra stock be increased to 40*l.*; and that premiums be given for frieze, home-made linen, stockings, &c., to be confined exclusively to the class of working farmers and their families who are the objects of the Society's bounty in the local Societies, and holding under 25 acres of land in their possession. On the motion of Mr. Lyle, the premium-sheet was referred back again to the sub-committee, with instructions to the secretary to have it printed as it then stood, and circulated amongst different members of the council, to ascertain their views upon the various portions of it, previous to the next general meeting of the Society on the 29th instant.

FLAX IMPROVEMENT SOCIETY OF IRELAND.

THE fourth annual meeting of this Society took place in Belfast on Friday, the 8th inst. The competition was very extensive—there having been no less than 132 entries of Flax; and the meeting was well attended. Amongst the machinery, a very superior machine for rolling Flax, previous to scutching, was exhibited by Messrs. Mac Adam, Curell, and Co., of the Soho Foundry, which attracted general attention. This machine is entirely of cast iron, and consists of a series of fluted rollers, of different sizes. It contains all the various improvements hitherto made in Flax rollers, and differs from them all in several particulars. The Flax passes but once through the machine, and is perfectly rolled. The rollers are so contrived that the Flax, in passing through them, receives a peculiar motion towards the end of the process, which has the effect of completely loosening the woody part. They are also so made that the fibre of the Flax cannot receive any injury; and by a new arrangement of the pressing levers the entire strain is taken off the machine the moment the Flax passes through. This rolling machine is driven by about half a horse-power, and can be attached to water-wheels, horse-machinery, or even driven by men. The following certificate has been forwarded from the Messrs. Herdmans, proprietors of the Sion Flax-mills, at Strabane:—

Sion Mills, Strabane, 7th Nov., 1844.

SIRS—After a month's trial of your bruising machine, we consider it the most perfect we have yet seen, both as to quality and number of the work done. It is easily driven and takes up very little space. We are able to bruise with it two tons of Flax straw per day; but we think the machine capable of bruising more.—Your obedient servants.

Messrs. Mac Adam, Curell, & Co.

The Marquis of Downshire, one of the Vice-Presidents of the Society, being called on the platform, addressed Mr. Mac Adam, and read the Report, from which we extract the following:—"The [illegible] grown in Ireland in [illegible] this year [illegible] hogsheads, of seven bushels each, [illegible] in 1843 were 37,000 [illegible] Other [illegible] cultivated crops [illegible] in 1843 were [illegible] Supposing [illegible] average production of 6 cwt. of [illegible] produce of Irish Flax, last year, [illegible] this year 30,000 tons. [illegible] 1844. The quantity of Flax grown in Ireland in 1841, the first year of the Society's existence, was about 22,000 tons; this year (1844) it is computed at 45,000 tons. There has thus been [illegible] during these three years, of 15,000 tons. [illegible] 8*l.* per ton, would amount to 675,000*l.* The improvements in quality, during this period, so [illegible] to all the processes of Flax, cannot have been [illegible] than the increase in quantity. [illegible] 100*l.* per ton, or one-fourth of the quantity grown. This would be 100,000*l.* more, which, added to the 675,000*l.* formerly given for the increase in quantity, makes, in all, 775,000*l.* [illegible] new channel would formerly have been paid, in bulk, to foreigners, but is now circulated among the farmers and labourers of Ireland. In consequence of the care now bestowed both on the growth and preparation of Irish Flax, its character is advancing; and your committee are now credibly informed that the yarns spun from Irish Flax are considered by manufacturers, as affording a better and more durable material for their fabrics than those spun from the generality of foreign Flax.

Saving of Flax-seed.—Your committee have been instrumental in bringing prominently before the farmers the great utility of Flax seed as food for all kinds of live stock. A prejudice has formerly prevailed against saving the seed, from an idea that it would injure the quality of the fibre. Almost everywhere through the country, this season, a large portion of the crop of seed has been saved; and the Flax does not seem to have deteriorated, when the operation was performed with care. Your committee have reason to believe that fully one-fifth of the Flax grown in Ireland, this season, has been rippled. The seed thus obtained for feeding, or has been sold for the oil-mills; and the total value of the above-named quantity, reckoning it at 3*l.* 10*s.* per acre, cannot be estimated at less than 60,000*l.* to 70,000*l.* Several large landed proprietors have, at great cost, erected scutch-mills on their estates, for the benefit of their tenantry, containing the most approved machinery.

The Factor System.—It has ever been the desire of your committee to introduce and foster the trade of purchasing Flax on the foot, as they conceive that this would at once obviate the objections to the results of managing the crop in districts of Ireland like the adjoining counties, where the agricultural population is fully employed. The gentlemen who engaged in this new branch of business, last year, from taking too much in hand, were unable to realise any profit, as much of the flax was greatly injured by their inability to have the different processes, on so large a quantity of Flax, managed by their infant establishments. This season, however, those who have purchased Flax on the foot have expressed themselves well satisfied with the result of their enterprise, and the statements for the prizes, which your committee offered to these gentlemen, can testify that such is the case. Mr. Galbraith's establishment at Lifford, has been of the most essential service, not only in giving profitable employment to members of persons in that neighbourhood, but in holding out such an example to the surrounding farmers in the neatness and care with which the Flax is handled, and the consequently vast improvement in the quality of the fibre, when ready for the market.

In the course of the evening of this day's proceedings Mr. J. Campbell made the following remarks on the Irish Flax trade:—"Now, many years ago, in the summer days, and winter evenings, the enlivening sound of the spinning-heel gladdened the hearts of the peasantry of this country, and continued to flourish. The enterprising Englishman saw that this simple operation could be more economically done upon a large scale, and by machinery. It were needless to inquire whether it would be better to have the trade as it was, or as it is now conducted. One thing, however, remains certain, that if this country did not keep pace with the improvement, and adopt spinning by machinery, it would soon lose it altogether, and possibly the other branches of the linen trade along with it. It was then that energetic, public-spirited and patriotic individuals, the Marquis of Castlewellan, and the Mulhollands of Belfast, determined to avail themselves of the improvements, and to put them for their own and their country's benefit. They commenced, and had carried on, all that day, that new branch of trade, in a manner creditable, as he hoped it had been profitable to themselves, and highly beneficial to the province of Ulster. Their example had been followed by others, and there were many numbers of concerns of this description in the north of Ireland, employing, as near as he could compute, 1,200,000*l.* paid, requiring besides, about half a million of floating capital, distributing 20,000*l.* per week, employing upwards of 12,000 men, women, and children, and indirectly, in vastly greater numbers, using 90,000 tons of coal yearly, which would employ about 30 sailing and 300 steamers to carry them. In England and Scotland, [illegible] was still of greater importance [illegible] Society, using about 400 tons [illegible] per week, [illegible] earth from 12,000*l.* to 15,000*l.*, or 15,500 tons per week, [illegible] at least 675,000*l.* [illegible] from the Meridian [illegible] having [illegible] him [illegible]

FARMERS' CLUBS.

[illegible] Farmers' Club [illegible] of this club [illegible] to receive the Report of the deputation [illegible] the Meeting [illegible] Mr. Edward Davis, late Croydon [illegible] Mr. Davis [illegible] a paper [illegible] subject of [illegible] Mr. Dickson read the [illegible] Spring Park Farm, consists of about 200 acres. The most striking feature [illegible] in draining the land was the care that had been taken [illegible] by grubbing hedgerows, &c., to lay the land open to the influence of the sun and air. The soil of this farm consists of black sand and beech gravel, with a subsoil of white sand and gravel. The moor-pan formerly consisted of exceedingly hard conglomerate masses of gravel and [illegible] sand, some of which were so large as to require six horses to draw them off the field. They are very similar to what is called

pudding-stone, and the soil is, evidently, from its appearance, a very inferior one, requiring pressure to consolidate it. Previous to Mr. Davis's occupation, a field termed Starve Acre, from its unproductive quality, could scarcely grow anything; but, under his management it has become the best on the farm, and has produced with thin sowing, no less than 5 qrs. of Wheat per acre. The whole of this apparently intractable land has been subsoiled, and a very large portion drained, by Mr. Davis, who, although his lease has only five years to run, will not drain a further portion, than 4 feet, deep, the labour alone costing him 9d. per rod. So convinced is Mr. Davis of the value of draining, that he believes even this expense will be fully repaid to him. His practice is to lay the land in ridges, varying from 18 to 24 feet in width. The seed having been got in, he generally runs Smith, of Deanston's, subsoil plough down each furrow, between the ridges, even through the drained land. With reference to the system of thin sowing, the deputation had an opportunity of seeing the stubbles that were still remaining unbroken. The growth of the stubble roots were remarkable, and were found to have tillered to from eight to ten stalks each. The next criterion for judging presented to the deputation was Mr. Davis's stack-yard, consisting of five large stacks of Wheat, two of Oats, two of Buck Wheat, one of Pulse, and three of Hay. Besides these stacks, there was a barn full of Pulse and another of Wheat and Barley. The appearance of the crops was excellent. The straw was exceedingly strong, and the ear was very fine. The Pulse crops were remarkably well podded. The Wheat was the Essex rough chaff, which Mr. D. had been told would not be grown on the system of thin sowing, as it had been said that thin sowing produced mildew, a disease to which this sort was particularly liable. Mr. D. states, however, that mildew is a disease that he has scarcely ever been troubled with. As the members may not all be aware of Mr. D.'s rotation, it is as follows:—

1st Year.	Rye	For green meat, and feeding off with sheep in April, May, June, and July, and followed by
"	Tares	
"	Mangold Wurzel	With a liberal dressing of farm-yard dung.
"	Swedes	
"	Cabbages	
"	Turnips	
2nd Year.	Oats or Barley, sown with Clover	
3rd Year.	Clover twice mown for Hay	
4th Year.	Beans or Peas	The Beans, save Turnips, drilled between the rows, which come into feed in September and October.
5th Year.	Wheat	

The quantities and periods at which he sows are the following:—

Rye	4 bushel	In August and September
Tares	1½	In August
Mangold Wurzel	6lbs.	In April
Swedes	1 quart	In May
Turnips	1	In July
Cabbages	1 every 2 feet,	In June
Oats	7 pecks	In Jan. Feb. and March
Barley	4	In Jan. Feb. March, and April
Wheat	2	In September and Oct.
Peas	2	In Dec. Jan. and Feb.
Beans	2	In September and Oct.

Mr. Davis's Rye and Tares for green feeding are sown in rows at 9 inches apart, all his white Corn at 10½ or 12 inches, his pulse at 27 inches, as are also his root crops, and Cabbages, on the ridge. The growing Tares, winter Beans, Wheat, Rye, and winter Barley, also Cabbages and Turnips, had a very healthy and flourishing appearance. The general appearance of the winter Barley and Rye, for spring feed, which is now a few inches above the ground, would lead a person passing by to the conclusion that the usual quantity of seed had been sown, till on examination he would find that it consisted of separate vigorous plants, which had each tillered out some seven or eight stems. Mr. D.'s general system of growing Turnips is that of planting double rows of Turnips and Cabbages alternately—a plan which has this advantage, that however untoward may be the weather, the sheep always find food in the Cabbages, which, although they draw the ground more than Swedes, yet produce a much larger weight of food per acre. These Swedes and Cabbages, considering the soil and the season, were exceedingly good. The number of stock upon this farm was 14 cows, 1 bull, 200 pigs, about 30 colts and breed mares, 200 fatting Bullocks on green crops and oil-cake, and 200 ewes in flock. Mr. Davis uses the Kentish turn-rest plough, Smith's subsoil plough, and Finlayson's harrow. He has discarded the old dished wheels of his waggons and carts, and substituted for them others, nearly straight, for their lighter draughts. He prefers the flail to the threshing machine. His cart-horses were all of the heavy Cleveland carriage breed, about 16 hands high, clean legged, with strong bone, and of great activity. Mr. H. has selected them from the Ivy Lane horse bazaar, which are sold off in London at the end of the season. They cost him from 12l. to 20l. each. At Bolderton Farm, the deputation had the opportunity of seeing Mr. Davis's Swedes drilled, and a Kentish plough at work in an adjoining field, ploughing to the depth of 12 inches. This farm, though of nearly similar soil, in other respects is of better quality than that of Spring Park, but, being let to speculating tenants, it had had four tenants within seven years. The crops appeared to have been equally successful here as at Spring Park. Selsdon Farm, however, offered the best criterion of Mr. Davis's mode of cultivation. Eleven years ago it was offered at 10s. per acre, tithe-free, and no one would hire it, only 8s. having been offered for it. It then consisted of a thin soil of about five inches on the chalk, comprising 136 acres of arable land, with 120 of poor park land. It never had had more than three stands for stacks in its stack yard; there are now 14 stands in this yard, which were last year filled, besides the barns. Mr. Davis has turned up six inches of pure chalk, which has all become disintegrated and mixed with the soil by the plough. He has been enabled to apply this system of cultivation to it, entirely dispensing with fallows. Upward of 50 fields, in which, under the old system, nothing would have thought of trying to grow. Turnips, Swedes, are to be seen on the Selsdon crop of Cabbages and Swedes, and the whole of the farm bears decided evidence of the great success of Mr. Davis's management, who states that he had of last year's growth 14 large stacks, and the barns full of corn, three stacks of Linseed and root crops for the fattening of 200 lamb sheep and 100 ewes with their lambs, besides 12 oxen. Ealing Farm, which has been under Mr. Davis's management for only nine months, presents no point worthy of particular observation, beyond those that have been mentioned with reference to the other farms, except the decided superiority of the last year's Wheat and straw, now cut, and threshed, as compared with those upon Mr. Davis's other farms. The leading features of Mr. Davis's system are deep ploughing, early and thin sowing, and frequent cultivation between the drills; which system, as applied by him to the farms above named, appears to have been most eminently successful. The following resolution was unanimously agreed to:—"That in the opinion of this meeting it is highly desirable, in a national point of view, that Mr. Hewitt Davis's system of drilling and cultivation, as expounded in his pamphlet, and reported upon this evening, by the deputation from this Club appointed to inquire into it, should receive the serious attention of agriculturists, and should be tried as generally as possible by way of experiment."—*Maidstone Gazette.*

Stapponey.—The following are extracts from a Paper on Keeping Farm Accounts, read by Mr. Amery at the late meeting of this Society:—"An accurate system of accounts affords the only safe index by which you can ascertain the value of new and improved modes of farming. It appears to me that only two accounts are necessary, namely, a day-book or journal, and a ledger, which may be kept in different parts of the same book; but in order to have the advantage of double entry, I very strongly recommend a cash account also. The first thing to be done in commencing any system of accounts is to take as accurate a valuation as possible of all produce on the farm, live stock, implements, fallows, seeds, &c.; and Michaelmas, when harvest is ended, is, in many respects, the most convenient period to do this. This valuation represents the capital at that time actually employed in the farm, and the amount thereof should be the first entry in the ledger to the debit of the farm, and the first entry in the cash account to the credit of cash, as due from the farm. All subsequent entries will be made from the journal or day-book as they occur, the farm being debited with all items of expenditure, labour, purchase of stock, implements, repairs, rent, taxes, interest on capital at 5 per cent., &c. &c., for which the cash account would have a corresponding credit, and being in like manner credited with all sales of produce and stock, and the value of produce consumed on the farm, except the keep of horses which are required to cultivate the farm, for which also the cash account would have a corresponding debit. At the end of every year, say from Michaelmas to Michaelmas, the ledger and cash account must be cast up and balanced; and, if they are kept correctly, the result of both will appear to be the same. Then, in order to ascertain the actual profit of the year, a fresh valuation must be taken, at the times' price, similar in all respects to that at the commencement of the year, taking care to deduct a per centage for the wear and tear of implements from their former estimated value, perhaps 15 per cent., and the difference between the amount of this last valuation so taken and the sum standing to the debit of the farm as due from it, shows the real amount of profit or loss for the year. This closes the amount of the last valuation, and will form the first entry of a new account for a succeeding year; the journal, ledger, and cash account will be then worked precisely as before."

Miscellaneous.

On the Analysis of Soils.—The following directions for selecting specimens of soil, or subsoil for analyses, are extracted from a paper issued from the Museum of Economic Geology, in the department of Her Majesty's Woods and Forests:—"Soils being generally the ultimate decomposed portions of subjacent mineral substances, whether hard rocks of various kinds, or clays, gravels, marls, &c., mingled either naturally or artificially with vegetable and animal matter, it becomes very desirable in collecting specimens of them that they should be accompanied by those of the hard rocks, clays, marls, gravels, &c., upon which they rest, and selecting galls for analysis from which to obtain their average specimens taken from the immediate soil, or subjacent hard rock, clay, gravel, &c. Specimens of the latter should be obtained, as near as possible beneath that spot whence the soil may have been selected, for it sometimes happens that the soil of a field varies in places from resting upon different kinds of materials. The soil above hard rocks is not unfrequently separated from them by broken angular fragments, the last decomposed portions of such hard rocks; specimens, therefore, of subsoil and subjacent mineral substances, should, in such cases, be taken from the solid hard rocks beneath, and not from these fragments, which have commonly suffered from much decomposition, to exhibit the real chemical composition of the rocks themselves. The quantity of soil taken as a specimen should weigh about a pound, which should be tied up in a canvas bag, and labelled. With respect to specimens of subsoils, if of marl, sand, or clay, particular weights about a pound should be tied up in a parchment bag labelled to correspond with the respective soils above them. If the subjacent rocks be hard, a piece also weighing about a pound, and fresh broken from the body of the rock as nearly as possible beneath the spot whence any specimen of soil may have been selected, should be wrapped in strong brown paper, labelled to correspond with the soil above it." The substances usually found in soils, are silica, alumina, carbonate of lime, carbonate of magnesia, phosphate of lime, phosphate of magnesia, phosphate of alumina, peroxide of iron, peroxide of iron, oxide of manganese, chloride of sodium, salts of potash and soda, and organic matter. Some of these are often absent, and the determination of others may sometimes be deemed superfluous; nevertheless it is our wish to make the process sufficiently complete to meet all ordinary cases. 1. The first step in the process is, properly to dry the specimen to be analysed over a water bath, at 212° Fahr.; a higher temperature than this should not be used, as it might cause the decomposition of some of the organic matter. The dried specimen is to be pulverized, sifted through a moderate wire sieve, and put into a stoppered bottle. 2. Five hundred grains of the dried specimen are to be spread out on a sheet of writing-paper, and exposed to the air for 12 hours; then weighed, and the increase of weight, if any, noted. The absorption of moisture from the air, if it take place to the extent of eleven or eight grains in the above quantity, may be considered a favourable indication. 3. One hundred grains of the dried specimen are to be introduced into a previously counterpoised bottle, containing hydrochloric acid, with the usual precautions; and when action has ceased, the amount of loss determined, which will be the carbonic acid resulting from the decomposition of the carbonates. 4. Two hundred grains of the dry specimen are to be put into a platinum crucible, and exposed to a red heat, being occasionally stirred, until on cooling it assumes a reddish appearance throughout. It is again to be weighed, and divided into two equal parts. 5. One of these parts is to be introduced into a counterpoised bottle, containing hydrochloric acid, and the disengaged carbonic acid estimated as before. If the quantity of carbonic acid thus deduced be less than that obtained before calcination, the difference must be added to the weight of the calcined product under operation, and this deducted from the weight before calcination, will indicate the amount of organic matter. 6. The other half of the residue left after calcination is now to be boiled in a flask with about an ounce of hydrochloric acid. By this means all the ingredients, excepting the silica and part of the alumina, will be dissolved, some of them being decomposed. The insoluble part is to be separated by filtration, washed well to remove acid, and dried. The solution, together with the washings of the insoluble powder is to be diluted to, and put aside for subsequent examination. This powder is to be finely powdered, and mixed with four times its weight of dried carbonate of soda. The mixture is then to be heated in a platinum crucible until it runs into a glass. The crucible and its contents being placed whilst warm in a *Wedgewood* dish containing distilled water, about an ounce of hydrochloric acid is to be added, and heat applied. More acid and water may be added, if necessary, until nothing more is dissolved. This being done, the solution and insoluble part are to be evaporated to dryness, in order to aggregate the silica held in suspension; and care must be taken during this operation that no hard lumps be left in the solution, as the silica sometimes forms a coating over such particles through which the acid will not get. The residue, after the evaporation, is to be heated with water mixed with about half an ounce of hydrochloric acid; the solution is to be filtered, and the insoluble part washed. The latter is the silica, which must be carefully burned to redness, and weighed when cool. The solution from which the silica has been separated, is to have a solution of ammonia added, which will throw down the alumina. This must be treated as the silica and weighed. 7. The solution *c* is still to be examined. For this purpose, add ammonia in excess, and dilute with strong acetic acid in considerable excess; and boil the mixture: phosphate of peroxide of iron, and phosphate of alumina, if present, will be precipitated, and will remain undissolved. Collect and weigh this precipitate, and label the solution *c*. Treat the precipitate with solution of caustic potash, which will dissolve the phosphate of alumina, and leave the phosphate of iron; separate, wash, dry, and weigh the latter. Add ammonia to the potash solution to throw down the phosphate of alumina, which in like manner to be collected and weighed. It must not be inferred that the phosphates of iron and alumina thus obtained, existed as such in the soil. The phosphoric acid may have been present in part in combination with lime or magnesia, while the iron may have been in the state of peroxide; and the alumina undissolved by but on dissolving the precipitate in the hydrochloric acid, the phosphate of lime or magnesia would be decomposed, and phosphates of iron and alumina formed. As this decomposition would always take place under the circumstances indicated, it next becomes a question, whether the equivalent proportions of peroxide of iron and alumina, or of phosphoric acid, existed in excess. To determine this point, divide the solution *c* into two parts; to one add a few drops of solution of perchloride of iron, which, if any soluble phosphates still remain undecomposed, will occasion a precipitate of phosphate of iron, in which case

it may be concluded that the whole of the iron originally in the solution has been obtained in the state of phosphate of iron. Continue the addition of perchloride of iron as long as a precipitate is formed, and treat this precipitate the same as that first obtained from solution *A*. If, on the other hand, no precipitate be formed from the perchloride of iron, it will be necessary to try whether there be more iron or alumina in the solution. In this case, add to the other half of the solution *c* liquid ammonia, so as to render it slightly alkaline; then add hydrosulphate of ammonia, which will throw down peroxide of iron, oxide of manganese, and alumina, if present. Collect and wash this precipitate, and label the solution *d*; dissolve the precipitate in hydrochloric acid, and boil the solution; add caustic potash in excess, which will throw down peroxide of iron, oxide of manganese, and alumina, but will again dissolve the last. The oxides of iron and manganese being removed from the solution, and ammonia added, the alumina will be precipitated. These precipitates are to be washed, dried, heated to redness, and weighed. 8. The quantity of manganese contained in soils is usually so small as to render its separation from the iron unnecessary. Its presence may be indicated by the black colour which the iron precipitate assumes on being exposed to the air, or by the smell of chlorine which is afforded on adding a few drops of hydrochloric acid to the precipitate. If thought desirable to separate these two oxides, let them be dissolved in hydrochloric acid, and precipitated carbonate of lime added, which will throw down the oxide of iron. Separate the precipitate; add oxalate of ammonia to the solution previously neutralised by ammonia, to remove lime, and then precipitate the manganese with caustic soda. Collect, dry, and weigh this, which is oxide of manganese. 9. The solution *d* may still contain lime, magnesia, and salts of potash and soda. Boil this solution to drive off any sulphuretted hydrogen it may contain, add oxalate of ammonia as long as a precipitate of oxalate of lime is formed. Collect, dry, and weigh this precipitate, and label the solution *e*. If the precipitate be dried at 212° it will contain one atom of water. 10. Add hydrochloric acid to solution *e*; evaporate it to dryness, and heat it to a dull red heat. Redissolve it in a little water; add some red oxide of mercury; evaporate again to dryness, heat it to redness, and treat the residue with water. Pure magnesia, if present, will remain, which weigh. 11. The chlorides of potassium and sodium have yet to be determined as well as the sulphate of lime. Boil 200 grains of the dry specimen in 10 ounces of distilled water; filter the solution, and wash the insoluble part, divide the solution into two equal parts; to one add nitric acid and then chloride of barium as long as any precipitate occurs; collect, wash, and dry this precipitate, which will be sulphate of baryta, obtained from the decomposition of the sulphate of lime. To the other half of the solution add nitric acid, and then nitrate of silver, as long as any precipitate occurs, which treat as in the former case. This will be chloride of silver, obtained from the decomposition of the chlorides of potassium and sodium.—*Pharmaceutical Journal.*

Steeping Seed.—The object in the present communication is merely to press a *veto* on steeping Turnip-seed previous to sowing; and I think the very numerous and repeated experiments I have made, and with uniformly decided results, will operate as a salutary caution against steeping Turnip-seeds in chemical solutions. My first experiments were made on the 21st June, and after white Stone Turnip had been steeped for 55½ hours in solutions of carbonate of ammonia, muriate of ammonia, phosphate of ammonia, and silicate of potash, with water simply, by way of comparison, it may suffice to say, that while the entire number of the seeds steeped in water germinated, and grew very well, not one of any of the rest germinated, with the solitary exception of three or four of those steeped in silicate of potash. Other chemical solutions were tried, and the period of steeping varied, but they proved uniformly fatal to the germination and growth of Turnip-seed. This seems of importance, as Mr. Campbell's steep, which contains sulphate and muriate of ammonia, has been recommended for Turnip-seed, as well as Wheat, Barley, and Oats. From my experiments, I deem much discrimination is essential in reference to chemical solutions, as steeps for various seeds. I have Blue Moreen Barley, which has tillered into 25 stems from seeds steeped in a particular chemical solution; and Mummy Wheat, which displays 16 stems, by being similarly treated. On the other hand, Kidney Beans, after being steeped 48 hours in a solution of phosphate of ammonia, entirely perished. Flax-seed was steeped for 28 hours in water, phosphate of ammonia, and sulphate of ammonia, germinated and advanced in growth, with little difference being perceptible. White Mustard and Portugal Onion were steeped for 28 hours in water, sulphate of ammonia, and phosphate of ammonia, and both Carrot and Onion seemed essentially invigorated and benefited by the solution of sulphate of ammonia.—*J. Morgan, in the Mark Lane Express.*

Notices to Correspondents.

Thanks to *Mr. Beaw* for his letter, which is too late for this Number.

ALLOTMENTS.—*Anon.*—See Number of the "Labourer's Friend" for August, September, October, and November, 1847.

ARTIFICIAL RAIN-MAKERS.—*Sesinus.*—Can any one inform us of the success of this instrument? Is there more than one kind of it?

BOOKS.—*Mr. Sproule* has applied to his bookseller for the name of the publisher of "Warren's Suggestions for Fattening, &c.," but it is not known. Will "A Constant Reader" kindly inform him?

BURNETT'S MATERIAL FOR PRESERVING WOOD, &c.—*Anon.*—This is the chloride of zinc.

COMPOST.—*T. E. L.*—Your compost is made up of materials the mixture of which will be advantageous. Charcoal-dust is a very useful element in all composts of materials whose decomposition produces ammonia.

DIBBLING.—*Querist.*—Eight inches by four are good intervals; two seeds in each hole.

FATTENING CATTLE.—*A. W.*—As you wish to consume all your Turnips on the land by sheep, you may profitably consume your straw by cattle in the yard upon straw and oil cake, 4 lbs. each daily, or try Mr. Warren's compound. How many head with 80 Turnips will it require to consume the straw of 90 acres of average bulk, between December 1st and May 1st?—This depends, of course, altogether upon the weather. If it be wet, 30 head of cattle would do it.

FOOT-ROT.—*J. M.*—The existence of foot-rot may be ascertained by the heat of the foot and the lameness of the sheep. The foot should be cut away sufficiently at the lower part to admit the escape of any matter that may be confined, and the diseased part should be touched, by means of a feather, with muriatic hydrochloric acid, which may be repeated if any fungus flesh grows on the part; if otherwise, the sore may be dressed daily with a powder composed of equal parts of sulphate of copper, alum, fine charcoal, and armenian bole. A dry lair is essential, and dirt and moisture highly prejudicial.—*W. C. S.*

FURROW-DRAINING.—*A. W.*—In 3-feet drains, to be filled with stones covered with straw, and no tiles used, fill to within 20 inches of the surface.

GRASS LAND.—*Subscriber.*—In last Paper we stated all we know of methods of extirpating Moss, viz, that caustic lime has been known to kill it. We must also say that we know cases in which it has failed to do so.

GURNEYISM.—*R. R.*—The influence of the light strawey covering which Mr. Gurney lays upon his pastures, appears, from published facts, to be singularly efficient in causing a rapid growth of Grass. We should be glad if any of our Cornwall subscribers would describe the subject to us. Your Grass will probably be somewhat earlier if you manure the land well.

LIME, &c.—*Querist.*—Apply it in autumn. The best way is to take it at once from the kiln, and divide it into heaps from the cart over the field, then cover up with a thickish coat of earth, and let it slake.

LINSEED.—*Querist.*—It must be crushed or ground some way or other; if you have not a suitable machine, and will not buy one, you must send the seed to the mill.

LIQUID MANURE. *Querist.*—If applied directly. Apply it on the young crop; the best way, however, is to carry it to the land in the farmyard manure.

LUCERNE.—*Delta.*—Your 10 rods of land, if they are statute measure, will require scarcely 1 lb. of seed. Sow in rows 12 inches apart, on deeply and well-tilled soil, in the month of April. We know only one kind. Cut it only once the first year—it will be ready about August. It will arrive at its full growth about the third year. You will need to manure it occasionally, and hoe and dig between the rows to keep the land clean.

MANURE.—*Querist.*—You had better mix the manure with earth in the field, not before carrying it thither.

POTATO SEED.—*A Farmer.*—Squeeze the ripe Potato Apples in water, strain all through a cloth, and dry the seed before the fire, and keep it in a dry place. In February, if you have the convenience of a hot-bed or hot-house, let it be sown thinly in flower-pots of rich light earth and covered very lightly; in a month or six weeks, or as soon as the young plants are an inch high, they are to be raised carefully and planted singly in small pots, and placed in a frame where they will have a very little warmth, and where they must have plenty of air and water as required until the middle of May, when they may be turned out of the pots into the open ground without breaking the ball. By this treatment the Potatoes will be so large the first year as to enable you to judge of their merits. If you cannot command artificial warmth, sow the seed in shallow drills of light rich earth, early in April, and transplant the young plants into rich earth in June, raise the Potatoes at the usual time, and treat them afterwards in the usual way: they will "prove themselves" the second year. —*Dublin Farmers' Gazette.*

POTATOES.—*Somersetshire Vicar.*—Your specimen appears similar to that figured in a Leader on the Horticultural side some weeks ago.

REARING CALVES.—*A. W.*—Give them an abundance of the milk of the cow, and give the latter such food as will tend to increase it, particularly its nitrogenised portion, *caseine*. Mangold Wurzel is one of the best roots for this purpose, and if sufficient milk cannot be obtained for the calf, Peas, made into a sort of broth, is, I believe, the best substitute. Moderate exercise is desirable both for the cow and the calf, which, however, should not be afforded, if the latter is intended for the butcher. *W. C. S.*

SEA INUNDATION.—*H. H.* is informed that I asked what would most readily restore fertility to Grass-land inundated by the sea. I also asked if it had ever been ascertained when any given quantity of salt ceases to be beneficial and becomes detrimental to vegetation, instancing the well-known fact that a thick dressing of salt on a gravel walk at the beginning of summer destroys the weeds for that season, but unless renewed every year tends to the increase of them. I also asked what would be likely to render mud taken out of a tide river useful as manure, with a view to counteract the superabundance of salt contained in it. Exposure to sun and air, in all cases of mud, is, I believe, very necessary to make it useful as manure, either in top-dressing or otherwise; but what would soonest assist the operation of the elements?—*H. D. P.*

SUBSOIL.—*Querist.*—It is better to divide your ground, and let your flock into successive portions, at successive periods. Sheep should not be put to ram till the second year.

*** As usual many communications have been received too late.

Markets.

SMITHFIELD, Monday, Nov. 22.—*Per stone of 8 lbs.*

	s. d.	s. d.		s. d.	s. d.
Best Beasts, Herefords, &c.	4 6	4 8	Best Down & Half-bred	5 0	5 2
Best Short Horns	4 10	4 8	Best Long Wools	4 10	5 0
2nd and inferior Beasts	4 0	4 4	Second and inferior Sheep	3 8	4 6
Calves	4 0	4 8	Pigs	3 8	4 4

Beasts, 2,600; Sheep, 27,600; Calves, 200; Pigs, 400.

Our supply of Beasts is again rather limited, which, owing to the favourable change in the weather, has caused a brisk demand, at an advance of 2d per stone on the prices of Monday last. Sheep are in good average supply, and the demand is steady, at last week's prices. Calves are in short supply, and sell readily at 4s to 4s 8d per stone. Pigs are in good supply, and sell slowly at 3s 8d to 4s per stone.

FRIDAY, Nov. 26.

We have rather more Beasts in than the best qualities will clear off this day, the inferior ones only supplied, although Monday's quotations are not realised. The second-rate Beasts, which constitutes very great portion of the supply and make a little less money. Short Horns, &c. as quoted. Short Horned Scots to-day and second quality 4s to 4s 6d. Deep supply of Sheep, but the demand is adequate. The best Downs, &c. are making 5s per stone, and Longwools 4s 10d to 5s 2d. Mutton is dull, and rather lower than on Monday, but the dead market having been pretty well cleared since Monday, we have a chance of getting all sold soon, at the under quotations. Veal trade is good; a very choice Calf is worth very nearly 5s per stone. Pork trade is steady.

Beasts, 2,600; Sheep, 27,600; Calves, 200; Pigs, 400.

Hay, Straw, Potatoes, Corn, Seeds, Wool, Smithfield.

POTATOES.—SOUTHWARK WAREHOUSES, Nov. 25.

Although the part which the supplies have been liberal from most of the shipping districts, and in consequence of the precarious character of the supply, there has been a ready demand for the best samples, but the second rate samples went off heavily.

HOPS, FRIDAY, Nov. 26.

This Day Sennight's obtainable terms at quite as much money.

PATTENDEN & SMITH, Hop-Factors.

MARK LANE, MONDAY, Nov. 29.

We find a moderate supply of Wheat from Essex, Kent, and Suffolk; the condition of which for the most part continues indifferent; best qualities being scarce are saleable at fully the rates of this day se'nnight; anything below is difficult to dispose of; there is very little demand for Foreign, where the following are late quotations. Fine Malting Barley is wanted, but other of the terms of last week; inferior continues neglected, with the exception of Foreign for grinding, which is in request. White bedding Peas are fully as dear; Maple dull. Grey is lower. Tick Beans are unaltered, but New are 1s. cheaper. Oats maintain the prices of Monday last.

FRIDAY, Nov. 26.

THE arrivals of English Wheat since Monday last's have been good, and such as were offered on the Market this day sold heavy sale at declining prices; business in Foreign has been very limited, but we observe no alteration in the value. The best samples of malting and also grinding descriptions of Barley are taken off on late terms, but secondary qualities of the former must be written 1s. cheaper. Beans and Grey Peas are unaltered; good breakers are inquired after, and the turn dearer. There is little doing in Oats, but Monday's prices are fully supported.

COVENT GARDEN, Nov. 30.—The supply of both Fruit and Vegetables has been well kept up during the week, but the market continues so be dull, as is generally the case about this time of the year. Of Fruit, Pine-apples are plentiful and good in quality. Hothouse Grapes are some what dearer than they were last week, and Portugals are also rather on the rise. Among Apples, the best dessert varieties at present in the market are, the Newtown Pippin, Blenheim Orange, and Wellington; and among Pears, the principal sorts for table are the Fulle Colmar, Old Colmar, Ne plus Meuris, Winter Nelis, and Chaumontelle. Melons are very scarce, and Cucumbers are nearly over for a season, as are also Quinces; but Medlars still continue plentiful. Oranges are becoming very plentiful, and Nuts of all sorts are pretty abundant. Vegetables have, generally speaking, not altered in price since our last report. Cauliflowers are, however, somewhat dearer; and Broccoli is slightly advanced in price. Turnips and Carrots are good and sufficient to meet the demand. Brussels Sprouts are likewise excellent in quality, as are also Savoys, Leeks, and Onions. Celery, Endive, and other salading are pretty plentiful. Cut Flowers chiefly consist of Euphorbia splendens, Poinsettia pulcherrima, Rondeletia speciosa, Pentas carnea, Bignonia venusta, Jasminum revolutum, Gaillia pinifolia, Heathe, Camellias, Cineraries, Chrysanthemums, Double Primulas, Heliotropes, Tulips, Roman, Narcissus, Neapolitan, Violets, and Roses.

FRUIT.

Pine Apple, per lb.	up to 5s 0d	Barberries, per half-sv.	2s 0d
Grapes, Hothouse, per lb.	2s 0d to 6s 0d	Cranberries, per dozen	1s 0d to 1s 6d

— Kidney, per bushel	6s 0d to 8s 0d	Small Salads, per punnet	3d to 6d
Turnips, per doz. bch.	2s 0d to 3s 0d	Watercress, per 12 sm. bun	3d to 6d
Carrots, per doz. bchs.	4s to 6s	Parsley, per doz. bunches	1s to 2s
Basil, per bunch	2d to 3d	— Roots, per bundle	1s to 2s
Horse Radish, per bundle	1s 0d to 1s 6d	Tarragon, Green, per bunch	2d to 3d
Savory, per bunch	1d to 2d	Green Mint, per bunch	2d to 3d
Spinach, per sieve	1s 0d to 2s 0d	Marjoram, per bunch	2d to 3d
Scorzonera, per bundle	1s to 1s 6d	Chervil, per punnet	3d to 6d
Salsafy, per bundle	1s to 1s 6d	Cuttle, per lot	1s to 2s
Leeks, per doz.	1s 0d to 2s 0d		
Garlic, per lb.	6d to 8d		

UNDER THE PATRONAGE OF HER MAJESTY.

J. G. WAITE, SEEDSMAN, &c., 1 and 4, Eyre-street Hill, Hatton Garden, London, embraces the present opportunity of returning his best thanks for the very liberal support he has hitherto received, and to assure his friends that no exertion shall be wanting on his part to merit a continuance of their favours.

J. G. W. most respectfully informs the public that Seeds of every description (with the exception of Carrots) are remarkably fine this season, and he will offer them at very low prices.

Waite's Queen of Dwarf Peas, per quart	7s. 6d.
A splendid new variety, growing only 3 feet high, producing a larger pod than any of the same habit; the seed is quite distinct from all others, and larger than any Dwarf Pea in cultivation. It has been grown at the Royal Gardens at Frogmore, and approved of as a fine new variety, and also at Her Majesty's tables for its superior flavour.	
Cuthill's Black Spine Cucumber, per packet of 100 seeds	5s. 0d.
Waite's Race Horse, do., 22 inches long, Black Spine, and wonderfully handsome, per packet of 20 seeds	5s. 0d.
True Beughwood Melon, of 25 do.	2s. 6d.
Pimelia spectabilis, new, of 5 do.	2s. 6d.
Calceolaria, from all the new spotted varieties, per packet	2s. 6d.
Anagallis Grandi do.	1s. 6d.
Pot roots of Dahlias of the finest varieties, including The Queen's Standard of Perfection, per doz.	10s. 6d.
Ranunculus, 100 roots in 100 fine sorts, with names, per 100	12s. 6d.

J. G. W.'s unrivalled-priced Catalogues of Seeds will be ready shortly, and can be had on application at 1 and 4, Eyre-street Hill.—November 30.

DUTCH HYACINTHS, for forcing, Single and Double at 4s. per dozen; also Narcissi, Crocuses, Tulips, Irises, Jonquils, Anemones & Ranunculuses; priced Catalogues of which will be forwarded per post, from AMEDEE CORBETT'S Italian and Foreign Warehouse, 13, Pall Mall.

Double Italian Tuberoses expected beyond of next month.

KNAP-HILL NURSERY, NEAR BAGSHOT, SURREY.

HOSEA WATERER (Brother and Successor to the late MICHAEL WATERER), respectfully begs to announce that the American Plants this year are remarkably well furnished with bloom; and with the other articles which are generally required for forcing, he has this season to offer very fine plants of the hardy Scarlet Rhododendrons. This Nursery has long been celebrated as containing the finest Collection of American Plants in the kingdom; independent of this, H. W. is a most extensive grower of Hardy Ornamental Trees and Shrubs, Roses, Forest and Fruit Trees; this may be inferred from the fact, that the Nursery extends over near 100 acres of land. The Knap-Hill Nursery is 24 miles from the Woking station of the South Western Railway.

All letters intended for this Nursery must be addressed Knap-Hill, near Bagshot, Surrey.—Nov. 30.

THOMAS JACKSON, of the Priory Farm, Chadwall, near Liverpool, Nurseryman, Florist, Forest Nursery, Seedsman, and others, that he has received a fine quantity of the Incomparable Hardy Green CUCUMBER, which was Advertised in the *Gardeners' Chronicle* of 23d March last. T. J. can refer any person to a respectable Nurseryman in this neighbourhood, as to quality and being genuine.—Price 2s. per Seed.—Nov. 30.

EDWARD BECK informs the Public that in consequence of the greatly increased demand for his SLATE TUBS, he is enabled to reduce the price of the following sizes about 10 per cent. He regrets the too frequent delay which has occurred in the execution of Orders. This he hopes to avoid in future by keeping a supply on hand.

Present Prices for Cash or Post-office order:—

14 inches	11s. 6d.	20 inches	22s. 6d.
15 inches	12 6	22 inches	25 0
16 inches	16 0	24 inches	32 0
18 inches	18 0		

Slate Works, Isleworth, Middlesex.

WHITNEY'S PATENT CLOTH for COVERING GRAPE-HOUSES, CUCUMBER or MELON PITS, &c. This Cloth is made expressly for the purpose of applying Whitney's Composition upon, and is much more durable than any other material when coated by it, beautifully white and transparent. The perfect success of Whitney's Composition for all Horticultural purposes cannot be more fully established than by stating, that, on the 16th of April last, a Black Hamburgh Vine was set in a border, the stem introduced into a house covered with Calico, and coated with Composition. On the 1st of Sept. a bunch of Grapes was cut weighing 10½ ounces, the fruit was finely coloured, and the flavour pronounced to be excellent. A sample was sent up to the Editor of the *Gardeners' Chronicle* for his inspection. The vine grew very luxuriantly, the foliage very fine, and the wood ripened exceedingly well. As a winter protection it is infinitely warmer than glass.

The PATENT CLOTH and COMPOSITION can be obtained of Messrs. Butler & Muckley, Covent Garden Market; Hurst & M'Mullen, Leadenhall Street; Warner & Warner, Cornhill; Barclay & Sons, Farringdon Street; and Hannay & Co., Oxford Street.—Wholesale and Shipping Agent, Mr. Bailey, Wolverhampton.

TO NURSERYMEN, SEEDSMEN, AND OTHERS.

LAVENDER HILL NURSERY, WANDSWORTH ROAD.

UNRESERVED SALE OF EXTENSIVE NURSERY STOCK.

MESSRS. PROTHEROE AND MORRIS are instructed by the Executors of the late Mr. RAMPLIN, to sell by Public Auction on the premises, Lavender-Hill Nursery, Wandsworth-road, near London, on Monday, Dec. 2d, and following days, at 11 o'clock on each day, the whole of the EXTENSIVE and VALUABLE NURSERY STOCK, comprising a large quantity of the finest Hardy Evergreens of all sizes (which have not particularly well out of this severe); Fruit and Forest Trees, Shrubs and American Plants; Hardy Herbaceous Plants; large and small Camellias; a very capital collection of Ferns, some of which are of extreme rarity; Garden Frames and Lights; Shop Fixtures and general Fittings of a Seed Shop and Counting House; Stock of Seeds of the present Harvest; Garden Implements, a useful Horse, Carts, Barrows, &c.; several thousand yards of Box Edging; about 200 Pollard Willows with their top and tops; Evergreen and other Hedges; also some growing Crops, as Mangold Wurzel and Turnips; together with many useful articles.

The whole will be sold without the least reserve, the premises having been disposed of for other purposes, and must be cleared before Christmas.

Catalogues will be ready one week prior to the Sale, and may be had on the premises; at most of the Seedsmen in London; at No. 45, Frith-street, Soho; and of the Auctioneers, Leytonstone, Essex.

FERNS.—The Collection of FERNS (in the approaching Sale of the Stock at the Lavender Hill Nursery) will be sold on the FOURTH DAY, viz., Thursday, December 5th, at 12 o'clock. Catalogues of this part can be had separately, on application.—Lavender Hill Nursery, Wandsworth-road.

PROTHEROE AND MORRIS.

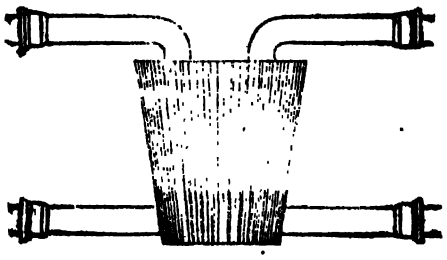
TO GENTLEMEN, NURSERYMEN, FLORISTS, & OTHERS.

MESSRS. PROTHEROE and MORRIS are instructed to submit to public competition, on the Premises, Wandsworth Lane, and Camberwell Nurseries, on Monday, December 16th, 1844, and following days, at 11 o'clock, by order of the Sheriff of Surrey, Without Reserve, the whole of the Choice Collection of GREENHOUSE PLANTS, consisting of fine Double Camellias, well furnished with bloom, Azalea Indica, Double Blood Erica in fine varieties; also the whole of the NURSERY STOCK. Further Particulars will be given in future advertisements. Catalogues may be had, one week prior to the Sale, on the Premises; of the principal Seedsmen; of Mr. J. C. Holmes, Solicitor, 108, Pangbourn Street, London; and of the Auctioneers, Leytonstone.

TO NURSERYMEN, SEEDSMEN, and OTHERS.

TO BE DISPOSED OF, A Most Desirable NURSERY, with the remainder of the Lease, about 9 years, situated 10 miles from the Metropolis, joining the Kensington Road, and within two minutes' walk of a railway station. The Nursery comprises from two to three acres of ground, well stocked with Evergreens, Shrubs, Fruit Trees, &c., also Greenhouse and Framing, with other Buildings convenient for the trade; with a Good Business in the centre of one of the best market towns in England. For further particulars, application to be made to Mr. Bruzzow, Seedsman, Knightsbridge; or Mr. Charlwood, Seedsman, Covent Garden; if by letter, post paid.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.



D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

BURBIDGE AND HEALY'S NEW BOILER and FURNACE for HORTICULTURAL PURPOSES.
Registered under 6 & 7 Vict., Cap. 65.
No. 130, FLEET STREET, LONDON.

BURBIDGE and HEALY respectfully inform the Horticultural Public that they have constantly on hand an extensive assortment of their new Boiler and Furnace Doors. In very numerous cases where they have been fixed, they have the highest testimonials of their complete success: for the further assurance of those who may require this apparatus, BURBIDGE and HEALY refer them to the Horticultural Society's Gardens, Chiswick; also to Mr. GLENDINNING, Garden Architect, &c. &c., Chiswick Nursery, in the same neighbourhood, where the apparatus may be seen in successful operation, in connection with their new Tanks. The following are the present prices:—

Plain Boiler.	Patent Door and Frames.	Fire-bars & Dead Plate.	Flue Door.	Damper.	Will heat of Pipe.	Forcing Pit, Length by feet.
in. ft.	s.	s. d.	s. d.	s. d.		
10 1 5	20	7 0	6 2	6	30 feet.	12 to 20
Ribbed Boiler.						
10 2 2	20	10 6	7 6	2 6	50 to 70 ft. 4 in.	Under 25 to 40
12 2 15	30	12 0	7 6	3 6	80 to 125 feet.	40 to 65
14 3 10	35	17 5	8 6	4 6	150 to 250 feet.	65 to 100
18 5 5	42	25 0	9 6	5 6	300 to 400 feet.	Warm a grapery 35ft. long, and a pit 50ft.
24 6 15	50	35 0	9 6	7 6	500 to 800 feet.	

If 3-inch pipe be used, one-third more. If 2-inch pipe, as much more.

The above quantities are rough estimates, which may be varied by enlarging or contracting the fire, or by regulating the fire door. It is possible to heat a much larger quantity of pipe with the boiler, but it would be done at great loss of fuel. The above proportions will be generally relied on as a near approximation to what is correct.

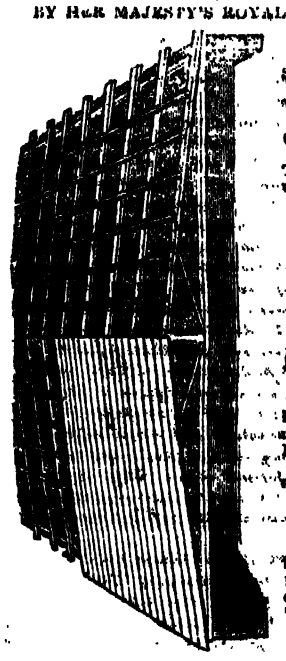
STEPHENSON AND CO., 61, Gracechurch-street, London, and 49, New Park-street, Southwark, Inventors and Manufacturers of the Improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their much-approved method of applying the flank system to Plant, Propagating Houses, &c. by which atmospheric heat is as well as bottom heat is secured to any required degree without the aid of pipes or flues. S. & Co. have also to state that at the request of numerous friends they are now making their Boilers of Iron, as well as Copper, by which the cost is reduced. These Boilers, which are now so well known, scarcely require description, but to those who have not seen them in operation, prospectuses will be forwarded as well as reference of the highest authority; or they may be seen at most of the Nobility's seats and principal Nurseries throughout the kingdom.

S. & Co. beg to inform the Trade that at their Manufactory, 49, New Park-st., every article requisite for the construction of Horticultural Buildings, as well as for heating them, may be obtained upon the most advantageous terms.

Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Balconies, Palisading, Field, and Garden Fences, Wire Work, &c. &c.

GUANO for SALE, in Bags of 1 cwt. each, just landed, with a succession of cargoes to arrive.—Successive years' experience has unquestionably proved that Genuine Guano is the simplest, cheapest, and best Manure within the reach of the Agriculturist. The only reasonable anxiety which now remains is to procure the Guano unadulterated, and to obtain such practical directions for using the treasure as shall fully develope its productive powers. To secure to buyers these indispensable requisites, with every purchase will be given a warranted chemical analysis of quality, and also a copy of the recently published Pamphlet, containing practical directions for using Guano as a Manure, illustrated by Agricultural Results in Detail.

Large parcels will be delivered direct from the ship or waterside premises; smaller quantities may be had at the warehouses, 24 and 25, Mincing-lane, or delivered within any reasonable distance at a trifling additional cost. Apply to JAMES CLARK, 24, Billiter-street, Fenchurch-street, London.



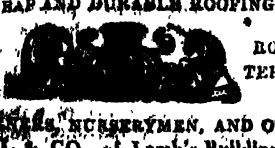
GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTHONY GIBBS AND SONS, LONDON; WM. & MYERS AND CO., LIVERPOOL; And by their Agents, COTESWORTH, POWELL, AND PRYOR, LONDON; GIBBS, BRIGGS, & CO., LIVERPOOL and BRISTOL.
47, Lime-street, Nov. 20, 1844.

IMPORTANT TO AGRICULTURISTS, &c.

ANALYSIS OF SOILS, MANURES, and all AGRICULTURAL PRODUCTS, are conducted by Messrs. MITCHELL and FRASER (late Mr. Mitchell), Analytical Chemists, with the view of ascertaining whether the Soil, to which it is proposed to grow any particular crop, contains all that is necessary to produce a luxuriant vegetation; also to estimate the relative value and parity of Manures, and the comparative worth of Farm Produce in general. Gentlemen instructed in Agricultural Chemistry. The course will comprehend the Elements of Analysis.—No. 5a, Hawley-street, Mornington Town.

DRAINING OF LAND.—THE WORKMAN'S LEVEL, invented by Mr. BAILEY DENTON, is made and sold, as approved by him, by Messrs. JONES, Opticians, 30, Lower Holborn, London, price 30s.

BY HER MAJESTY'S ROYAL LETTERS PATENT.



PATENT ASPHALTE ROOFING, saving half the Timber usually consumed.
Weight, 2½ lbs. per square of 100 feet.
Cost, 2s. 4d. per square of 100 feet.
The above Material has been used and approved of by the NOBILITY, GENTRY, and AGRICULTURISTS generally, as a ROOFING & COVERING to SIDES of FARM BUILDINGS.
Its advantages are LIGHTNESS, DURABILITY & ECONOMY.
Being a non-conductor, it is a PROTECTIVE MATERIAL TO PLANTS, and is now in use at the ROYAL HORTICULTURAL GARDENS, Chiswick.
It can be had of any Agent in London, Paris, or Brussels, and of the Inventor, at the Works, Millbank-street, Westminster.
THOMAS J. CROGGON, 6, Tilney-court, Fenchurch-st., London.

DR. HALLETT'S DRY SOLUBLE FERTILIZERS are, considering their power, the cheapest Manures in use, for they are entirely composed of the Phosphates and other Salts of Ammonia, and other acknowledged powerful fertilizers. They are fairly before the Public as tried things (see No. 33 of the *Gardeners' Chronicle*, &c.). 4 cwt. of either has been found equal to nearly 20 tons of ordinary horse-manure. They are applicable to all sorts of field and garden crops. No. 1 for heavy top growth, as Oats, Hops, &c. No. 2 is for all roots, and a sure preventive of the Fly in Turnips. Price of each, 10d. per ton, or 1½d. per cwt.

DR. HALLETT'S CONCENTRATED LIQUID FERTILIZER is extensively used by Gardeners for improving the size and flavour of fruits and vegetables, and the colours, and perfecting the seed of flowers. Sold in quarts at 1s. 6d., and in bottles, six times the size, at 7s. 6d. Each quart requires 32 gallons of water, to reduce it for use.

Agents for the above: London—Pettergill, Thames-street; Mr. G. Fisher, the Factory, Broadwall, Blackfriars; Messrs. Warner & Warner, 25, Cornhill; Hurst & M'Mullen, 6, Leadenhall-street; Winsland, Poultry; Page & Co., St. Peter's Alley, Cornhill; Pollard and Son, Norwich. Norfolk—Mr. W. Hovell, Yeldford. Leicester—Mr. Ellis and Co. Gloucestershire—Mr. Bostock, Fairford. Devonshire—Mr. Howard, Plymouth. Wolverhampton—Mr. King, Dudley. Glasgow—Mr. D. T. Jackson, Hartshorne, Sandyford, Stockton, and Newcastle—Page & Co. Dublin—Green & Co. Further respectable Agents wanted.

CHEAP AND DURABLE ROOFING.

BYFIELD'S ROYAL LETTERS PATENT.

TO GARDENERS, NURSERYMEN, AND OTHERS.

J. M'NEILL & CO., of Lamb's Buildings, Bunhill-row, London, Manufacturers, and only Patentees of IMPROVED PATENT ASPHALTED FELT, for Roofing Houses, Sheds, Verandahs, &c., and for Protecting Plants, and Covering Garden Frames, beg to call the attention of Gardeners and others to their superior article, which has been exhibited at the Great Agricultural Shows of England, Scotland, and Ireland, and pronounced the Prize for being the best and cheapest article for roofing, &c. It has been tested in the gardens of several noblemen and gentlemen in the neighbourhood of London, and in different parts of the country, to whom reference can be made. The Felt is impervious to rain, snow, and frost, and a non-conductor of heat and sound. Its advantages are Lightness, Warmth, Durability, and Economy.—Price ONLY ONE PENNY PER SQUARE FOOT.

Samples, with directions for laying on, and testimonials as to its merits, sent free to any part of the town or country.—Patent Felt Works, Lamb's Building, Bunhill-row, London.

I.

In post 8vo, price 10s. 6d., handsomely bound in a new kind of cloth, silver gilt; or 9s. boards,

IMAGINATION and FANCY; or, Selections from the best English Poets, Illustrative of those First Requisites of their Art, with Markings of the best Passages, Critical Notices of the Writers, and an Essay in Answer to the Question, "What is Poetry?" By Leigh Hunt.

"This volume is handsomely printed, and beautifully bound in a new style of exquisite delicacy and richness. To institute a comparison with the contents of the Annuals would be absurd; at any degree of distance—there is no more relation between them than between a street lamp and a fixed star; but in external beauty 'Imagination and Fancy' equals any gift-books that have appeared; and it will form a more enduring memorial than any other volume that might be selected as a gift for the ensuing season."—*Spectator.*

II.

Just published, Sixth Edition, in 3 vols. fcap. 8vo, beautifully illustrated, price 7s. 6d. each, in a handsome and uniform cloth binding; or 10s. 6d. handsomely bound in morocco,

NOTICE IS HEREBY GIVEN that in future the MEETINGS of the GARDENERS' BENEVOLENT INSTITUTION will be held at the LONDON COFFEE-HOUSE, Ludgate hill.—By order, Rowe. R. Cutler, Secretary, 97, Farringdon street.

THE ARBORETUMS QUEEN'S-ELMS, BROMPTON, NEAR LONDON, AND EAST COWES, ISLE OF WIGHT.

RAMSAY BROTHERS, Landscape Gardeners, Contract Planters, Ground Workmen, &c.

Plans and Estimates submitted, and works contracted for in any part of the kingdom.

J. B. SMITH, having purchased the rare and valuable STOCK-IN-TRADE of the executors of his late father, begs leave to inform the Nobility, Gentry, and Amateurs, that he intends carrying on the Business as hitherto, and shall be glad to be favoured by their kind commands, which shall ever meet his best attention. A choice collection of Rhododendrons, Azalea Indicas, Hardy Azaleas and Ghent Azaleas, Camellias, Roses, Pelargoniums, Liliums, &c., including the most novel and approved varieties; a priced list of which may be had on application. A liberal discount for cash. A remittance or reference from unknown correspondents is solicited.

Norbiton Nursery, Kingston, Surrey, Dec. 7.

KNAP-HILL NURSERY, NEAR BAGSHOT, SURREY.

HOSEA WATERER (Brother and Successor to the late Michael Waterer), respectfully begs to announce that the American Plants this year are remarkably well furnished with bloom; and with the other articles which are generally required for forcing, he has this season to offer very fine plants of the hardy Scarlet Rhododendrons. This Nursery has long been celebrated as containing the finest Collection of American Plants in the kingdom; independent of this, H. W. is a most extensive grower of Hardy Ornamental Trees and Shrubs, Roses, Forest and Fruit Trees; this may be inferred from the fact, that the Nursery extends over near 100 acres of land. The Knap Hill Nursery is 24 miles from the Woking station of the South Western Railway.

All letters intended for this Nursery must be addressed Knap-Hill, near Bagshot, Surrey.—Dec. 7.

ROSES.

MESSRS. LANE AND SON, Great Berkhampstead, Herts, have in extensive and well-grown Stock of Standard and Dwarf Roses, which they are enabled to offer at the following prices, the selection being left entirely to themselves, viz.:—

DWARFS, good old sorts without names, on own roots	30s. per 100
Ditto ditto with names, in pairs, on own roots	50s. per 100
Ditto superior ditto	12s. to 30s. per doz.
STANDARDS, first rate	10l. per 100
Ditto ditto	24s. to 30s. per doz.

They have also an immense Stock of Roses in pots for greenhouse culture, at from 18s. to 30s. per doz. Likewise numerous others at a much lower rate, but which they could not confidently recommend.

Rose Catalogues for 1844-5 may be had on application, to the Nurseries, inclosing a 2d. postage stamp.

Great Berkhampstead, Dec. 7, 1844.

THOMAS JACKSON, of the Priory Farm, Childwall, near Liverpool, begs to inform Nurserymen, Seedsmen, and others, that he has saved a fine quantity of the Incomparable Hardy Green COLEWORT, which was Advertised in the *Chronicle* of 23d March last. T. J. can refer any person to a respectable Nurseryman in this neighbourhood, as to quality and being genuine. Price 2s. per lb.—Dec. 7.

J. WHYTE begs to inform the Public that he has now ready for Sale some fine new SEED of his well-known dark and delicious BEET. Price, per lb., 3s.; or 1s. 6d. per oz.; to be had of the grower, Isleworth.

TO THE SEED TRADE.

J. G. WAITE, Wholesale Seedsman, begs to inform the Trade, that his PRICED CATALOGUE is now ready, and can be had on application.

3 and 4, Eyre-street-hill, Hatton Garden, December 7.

THE TRUE FASTOLFF RASPBERRY.

GREAT YARMOUTH NURSERY. NORFOLK, 1844.

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN, HIS GRACE THE DUKE OF RUTLAND, HIS GRACE THE DUKE OF MARLBOROUGH, THE EARL OF HARRINGTON, THE EARL OF LIVERPOOL, THE LORD BISHOP OF LONDON, LORD VISCOUNT LORTON, LORD SONDES, &c. &c., as well as by the HORTICULTURAL SOCIETY OF LONDON.

YOUELL AND CO. beg to announce they are again able to supply fine canes of the above truly excellent variety, unequalled for the size of its fruit and richness of flavour; prices as follow —

Packages containing 100 Canes	.	£2	0	0
Ditto ,, 50 ,,	.	1	1	0
Ditto ,, 25 ,,	.	0	12	0

For particulars of the above, see Y. & Co.'s Advertisement of Nov 9th.

YOUELL AND CO. take the present opportunity to state that the above unequalled RASPBERRY is to be obtained only at their Nursery or of their Agents (as follows) and they recommend their friends to be cautious of whom they purchase, as another Raspberry, under the above title, has been substituted by certain parties as the "true variety" They also publicly deny the truth of Mr Rivers' statement, "that the fruit upon which Dr. Lindley pronounced his opinion was gathered in what he terms the 'Filby Garden.'"

LIST OF AGENTS.

Bury St. Edmunds—Mr R. Pettit; Canterbury—Mr W. Masters; Carlisle—Messrs Little and Ballantyne; Chichester—Messrs. Newman and Co., Cliff Vale, near Leek, Staffordshire—Mr. T Fox, Cork—Messrs. Palethorpe; Halifax—Mr. W Throp, Jersey—Mr. B. Saunders; Leeds—Messrs Ely and Son, Rothwell Haigh, London—Messrs Flanagan and Son, No 9, Mansion House-street, and Messrs Noble, 152, Fleet street, Liverpool—Mr James Cuthbert, 12, Clayton square, Manchester—Mr. H D Cormack, Nottingham—Mr. J. F. Wood, The Coppice, Peterborough—Mr. John White, Penzance—Mr. J Fox, Plymouth—Mr W. E. Rendle, Sheffield—Messrs. Fisher, Holmes, and Co., Southampton—Mr. James Ingram; Stafford—Mr J Sandy; Torquay—Mr J. Morgan, Wakefield—Mr. W Barratt, Waterford—Messrs. Fennessey and Son, Westerham, Kent—Mr I Cattell; Wexford—Mr. James Harpur, York—Messrs. I. and I. Backhouse.

YOUELL'S CELEBRATED TOBOLSK RHUBARB, the earliest sort known; fine roots, fit for forcing, 12s. per dozen. For Particulars see their Advertisement of Nov. 2.

Finest Imported DUTCH HYACINTHS, 6s., 12s. and 18s. per doz.; for Particulars of which, together with the Extensive and Select Collection of CARNATIONS, PICOTEES, and PINKS, see their Advertisement of Nov. 9.

Great Yarmouth Nursery, Dec. 7, 1844.

THE FILBY, or FASTOLFF RASPBERRY — At the request of some gentlemen living in the neighbourhood of Yarmouth, T. RIVERS begs to submit the history of this really excellent Raspberry to the public. In the year 1814 Colonel Lucas, of Filby, a place lying between Norwich and Yarmouth, discovered a Raspberry plant growing under an old Laurel hedge in his garden. His attention was drawn to it, and he soon found it to be a superior and delicious variety, so that in a short time every other sort was ejected from his garden, and this alone cultivated. It was not, however, till 1826 that he allowed his gardener to part with it, who then gave canes to his neighbours, and by this means it got to be cultivated in Caistor, Ormsby, and, in fact, in all the neighbourhood, under the name of the Filby Raspberry, to the exclusion of all other sorts. It has latterly often been called the Caistor Raspberry, from the Market Gardeners growing it in that parish. In Caistor is an old castle in ruins, that formerly belonged to the Fastolff family the latter name was given to the variety by Youell and Co., when they first began to sell the canes. The fruit upon which Dr Lindley pronounced his opinion was gathered in the Filby garden, now the property of the Rev. G. Lucas, who authorises and permits the publication of the above facts; and has also permitted his Gardener to supply the Canes after this date to T. RIVERS only.

Canes are sold at 30s. per 100, or 6s. per score, carriage paid to London. Charge for package, for small parcels, 2s., for large do., 1s. to 4s. 6d. Orders to any amount can be executed. The Trade price will be given on application.

Sawbridgeworth, Herts, Dec. 7, 1844.

DUTCH HYACINTHS for forcing, Single and Double at 4s. per dozen; also Narcissi, Crocuses, Tulips, Irises, Jonquils, Anemones, Ranunculuses; priced Catalogues of which will be forwarded per Post, on application to Messrs. Lamarie Cormerais Italian and Foreign Warehouse, 12, Pall Mall.

Double Italian Tuberose roots expected the end of this month.

THUNBERGIA GRANDIFLORA.—Plants of this new and beautiful Climber, with rich purple with a golden eye, 5s. and 7s. 6d. each. Also strong Bushy Plants of Superb Seedling Cinerarias, well budded and forward for flowering, containing every shade of dark and light blue tints, furnishing to the Greenhouse, Conservatory, or Drawing-room, an ornamental and splendid continuance of elegant bloom throughout the winter months, 6s., 9s., and 12s. per dozen.

Packets of the best mixed seed of do.		s.	d.
Do. that large Antirrhin Brownii		2	6

Application, including Post-office order or stamps, will be carefully executed.—Direct to Michael Banner, Senior, Cambridge Nursery, Cambridge.

TO MELON GROWERS.

FISH'S MANCHESTER CANTALOUPE and HARDY GREEN-FLESHED MELONS. The above are recommended to all Melon-growers, as independent of the good quality of the Fruit, they are so easy to require comparatively little attention, a fact of considerable importance where fuel is expensive, and fermenting material a scarce commodity. Both sorts were awarded Certificates of Merit at Regent-street, London; the Cantaloupe on the 7th of May, described as "good early fruit," and the Green-fleshed on the 4th of June, described as "capital green Melon, high flavoured, and weighing nearly 5 lbs." The Cantaloupe grows from 4 to 6 lbs. in weight. Fruit was exhibited in July at Chiswick, weighing 4 lbs. 14 oz., and the fifth crop is maturing in November, from the same plants cut from in May. Specimens of the Green-fleshed, from the same plants cut from in June, were exhibited at Regent-street, on the 1st Oct., weighing 3 lbs. each. These have been grown on slung beds, as described in the *Chronicle* of the 7th May and 1st October.

Youell and Co. having purchased of Mr. Fish the entire stock of Seed of the above most desirable Melons, for the first time offer it to growers, being fully confident of its realising all the merits ascribed to it. Sealed packets, containing three seeds of each, 6s., sent per post, free.

Great Yarmouth Nursery, Dec. 7, 1844.

FRANCIS AND JAMES DICKSON, Nurserymen, Chester, have much pleasure in submitting the above List of VALUABLE EVERGREENS, &c., of which they at present possess a considerable stock of exceedingly healthy and well grown plants. *** Orders will command every attention.

Newton and Upton Nurseries, Dec. 7.

TO THE CULTIVATORS OF ROSES.

R. B. BIRCHAM, Hedenham Rosery, Bungay, Suffolk, begs to offer the following Select ROSES, which he can with confidence recommend, as possessing superior quality. A purchaser selecting 12 different kinds from this list, R. B. B. will be happy to supply at 20s. The plants are strong and healthy, and varying in height of stem from 1½ feet to 3 feet.

Agnes Sorel	Aurelie Lamare	Les Cases
Donna Sol	Bracis	Idalize
Duchess of Kent	Buffoon	Jambart
Duchesse d'Orleans	Crivelle	Julie
Emerance	Duc de Trevisé	La Splendeur
Illustre Beauté	Epic	Nelly

To the owner of the best Mare and Foal for Agricultural Purposes, 20*l.*; to the owner of the second-best do., 10*l.*—6. To the owner of the best two years old Filly, 10*l.*—7. To the owner of the best Thorough-bred Stallion, which shall have served mares at a price not exceeding 3 guineas (and with a groom's fee of not more than 5*s.*) in the season of 1845, 30*l.*

SHEEP.

Prizes for Improving the Breed of Sheep.—1845.

Lincolns.—Class 1. To the owner of the best Shearling Ram, 20*l.*; to the owner of the second-best do., 10*l.*—2. To the owner of the best Ram of any other age, 20*l.*; to the owner of the second-best do., 10*l.*—3. To the owner of the best pen of five Shearling Ewes, 10*l.*; to the owner of the second-best do., 5*l.*

Leicesters.—Class 1. To the owner of the best Shearling Ram, 20*l.*; to the owner of the second-best do., 10*l.*—2. To the owner of the best Ram of any other age, 20*l.*; to the owner of the second-best do., 10*l.*—3. To the owner of the best pen of five Shearling Ewes, 10*l.*; to the owner of the second-best do., 5*l.*

Southdown Sheep.—Class 1. To the owner of the best Shearling Ram, 20*l.*; to the owner of the second-best do., 10*l.*—2. To the owner of the best Ram of any other age, 20*l.*; to the owner of the second-best do., 10*l.*—3. To the owner of the best pen of five Shearling Ewes, 10*l.*; to the owner of the second-best do., 5*l.*

Long Woolled Sheep. (Not qualified to compete as Leicesters.)—Class 1. To the owner of the best Shearling Ram, 20*l.*; to the owner of the second-best do., 10*l.*—2. To the owner of the best Ram of any other age, 20*l.*; to the owner of the second-best do., 10*l.*—3. To the owner of the best pen of five Shearling Ewes, 10*l.*; to the owner of the second-best do. do., 5*l.*

Sheep best adapted to a Mountain District.—Class 1. To the owner of the best Ram of any age, 15*l.*; to the owner of the second-best do., 10*l.*; to the owner of the third-best do., 5*l.*—2. To the owner of the best pen of Ewes of any age, 10*l.*; to the owner of the second-best do., 5*l.*

PIGS.

Class 1. To the owner of the best Boar of a large breed, 10*l.*; to the owner of the second-best do. do., 5*l.*—2. To the owner of the best Boar of a small breed, 10*l.*; to the owner of the second-best do. do., 5*l.*—3. To the owner of the best breeding-Sow of a large breed, 10*l.*—4. To the owner of the best breeding-Sow, of a small breed, 10*l.*—5. To the owner of the best pen of three breeding Sow-pigs, of the same litter, above four and under ten months old, 10*l.*

AGRICULTURAL IMPLEMENTS.

A sum not exceeding 20*l.*

Cheese.—To the exhibitor of the best coll. of Cheese (of any kind) made within the district, 10*l.* To the exhibitor of the second-best do., 5*l.*

Extra Stock, Roots, and Seeds.—For Extra Stock, of any kind not shown for by the foregoing Prizes, and for Roots, Seeds, &c., Prizes may be awarded at the discretion of, by the Committee and Judges, upon sums not exceeding in the whole 50*l.*

Any New Implement.—For the invention of any new Agricultural Implement, such sum as the Council may think proper to award.

Seed Wheat, Barley, and Oats.—I. Twenty Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 14 bushels of White Wheat, of the harvest of 1844, and grown by himself.

II. Fifteen Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 14 bushels of Red Wheat of the harvest of 1844, and grown by himself.

III. Ten Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 14 bushels of spring Wheat, of the harvest of 1844, and grown by himself.

IV. Ten Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 14 bushels of Barley for malting, of the harvest of 1844, and grown by himself.

V. Ten Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 14 bushels of Oats, of the harvest of 1844, and grown by himself.

Competitors are requested to bring with their Wheat, Barley, or Oats, specimens, fairly taken, of the sample in the ear, with the whole of the Straw, in a sheaf not less than one foot in diameter, and with the roots attached.

[12 bushels of the Wheat, Barley, or Oats will be required by the Director for Reference, and one of the remaining bushels of each variety will be exhibited, as a sample to the public, the other being kept for examination with the growing crops next year. At the General Meeting in December likely the Prizes will be awarded.]

The two best Samples of [illegible] Barley, or Oats, without [illegible] of the cases, between the [illegible] shall be selected by the [illegible] Shrewsbury; and will be [illegible] Council (the winter Wheats in the autumn of 1845, and the spring Wheat not earlier than the 1st of March, 1846), by four farmers, who will make their report [illegible] the Prizes will be awarded, provided there be [illegible] of the samples. 10*l.* will be given [illegible] to each exhibitor whose [illegible] for the Barley or Oats.

*** No variety which has [illegible] previous Show shall be qualified to compete in the same [illegible]

ESSAYS AND REPORTS ON VARIOUS [illegible]

1. *Farming of Nottinghamshire.*—Twenty Sovereigns, or a Piece of Plate of that value, will be given for the best Report on the Farming of Nottinghamshire. Competitors will be expected to describe the different varieties of soil which prevail in the county, the ordinary modes of farming and courses of cropping adopted accordingly in its various districts, and to state how far any peculiar practices in its husbandry are or are not justified by peculiarities of soil or climate. They will also be expected to state what improvements have been made in the farming of Nottinghamshire since the Report of Mr. Robert Lowe in the year 1798; and especially to point out what further improvements ought to be effected, either by better farming on land already cultivated, or by taking new land into cultivation.

2. *Farming of Cornwall.*—Fifty Sovereigns, or a Piece of Plate of that value, will be given for the best Report on the Farming of the County of Cornwall. Competitors will be expected to describe the different varieties of soil which prevail in the county, the ordinary modes of farming and courses of cropping adopted accordingly in its various districts, and to state how far any peculiar practices in its husbandry are or are not justified by peculiarities of soil or climate. They will also be expected to state what improvements have been made in the farming of Cornwall since the Report of Mr. J. H. Worgan, in the year 1811; and especially to point out what farther improvements ought to be effected, either by better farming on land already cultivated, or by taking new land into cultivation.

3. *Farming of Kent.*—Fifty Sovereigns, or a Piece of Plate of that value, will be given for the best Report on the Farming of the County of Kent. Competitors will be expected to describe the different varieties of soil which prevail in the county, the ordinary modes of farming and courses of cropping adopted accordingly in its various districts, and to state how far any peculiar practices in its husbandry are or are not justified by peculiarities of soil or climate. They will also be expected to state what improvements have been made in the farming of Kent since the Report of Mr. John Boys, in 1805; and especially to point out what farther improvements ought to be effected, either by better farming on land already cultivated, or by taking new land into cultivation.

4. *Heath Land.*—Twenty sovereigns, or a piece of plate of that value, will be given for an account of the best method of reclaiming heath-land. Competitors will be required to describe methods which have been successfully adopted in the reclaiming of heath-land, reference being had especially to the following points:—1. The mode of breaking up, whether by paring and burning, or by simple ploughing. 2. The application of lime. 3. The course of cropping. 4. The conversion of heath-land into pasture, where either the steepness of the land, or its elevation above the sea, does not allow the culture of corn.

5. *One-Horse Carts.*—Ten Sovereigns, or a Piece of Plate of that value, will be given for the best Essay on the advantages of One-horse Carts. Competitors will be required to point out the saving in horse-labour, and other advantages which undoubtedly arise from substituting 1-horse carts for waggons.

6. *Catch-Meadows.*—Twenty Sovereigns, or a Piece of Plate of that value, will be given for the best Essay on Catch-Meadows. Competitors will be required to describe the best and cheapest method of forming water-meadows on the sides of natural slopes, as practised in Somersetshire and Devonshire; the mode of managing them, and of applying their produce; the increase of value thereby given to unproductive hill-sides; and to state how far this mode of improvement might be applied to the mountainous districts of Wales and the North of England.

7. *Fences.*—Twenty Sovereigns, or a Piece of Plate of that value, will be given for the best Essay on Fences. Competitors will be required to describe the best and neatest methods of maintaining hedges, whether for arable or for grazing ground; and to point out how far the present fences in various parts of England are injurious to the farmer, whether by their size, their excess in number, or the over-abundance of timber which they contain.

8. *Fattening Cattle.*—Ten Sovereigns, or a Piece of Plate of that value, will be given for an account of the best method of fattening cattle; as to the places in which they are kept, large or small yards or stalls, as well as the food, roots, hay, &c. on which they are fed during the time of fatting.

9. *Tile-yards.*—Twenty Sovereigns, or a Piece of Plate of that value, will be given for the cheapest and best method of establishing a Tile-yard. Competitors will be required to attend to the following points:—1. Mode of working the clay, according to its quality. 2. Machine for making the tiles. 3. Sheds for drying the tiles. 4. Construction of the kiln. 5. Cost of forming the establishment. 6. Cost of the tiles when ready for sale.

10. *Curing Butter.*—Fifty Sovereigns, or a Piece of Plate of that value, will be given for the best description of the Dutch method of salting butter; pointing out the causes of its superiority to other salted butters.

11. *Experiment in Agriculture.*—Twenty Sovereigns, or a Piece of Plate of that value, will be given for an account of the best Experiment in Agriculture.

These Essays must be sent to the Secretary, at 12, Hanover-square, London, on or before March 1st, 1845.

Twenty Sovereigns, or a Piece of Plate of that value, offered by the Right Hon. Lord Kenyon, will be given at the Annual Country Meeting of the Royal Agricultural Society, to be held at Shrewsbury in 1844, for the best account of the Use of Gorse for the Food of Cattle, Horses, or Sheep, founded on actual experiment. Competitors will be required to state the following points: 1. The quality of land on which the Gorse is grown. 2. The age of the plant when cut. 3. The mode and expense of cutting. 4. The mode and expense of preparing for food. 5. The mode of feeding with Gorse, and the quantity of other food given therewith.

Essays competing for this Prize must be sent to the Secretary, at 12, Hanover-square, on or before March, 1845.

1. *Rules of Competition for Prize Essays.*—1. All information contained in Prize Essays shall be derived from experience of observation, and not on simple references to books, or other sources. 2. Drawings, specimens, or models, throwing light on the subject to which the Essay shall relate, shall accompany all Essays competing for Prizes. 3. All competitors shall address their Essays, post paid, to the Secretary, at 12, Hanover-square, London, on or before the day on which the Essay, shall be received. 4. The Prizes shall be awarded by a Committee of Judges, to be appointed by the Council for the time being, shall have power to call for such information as they may think necessary for determining the Essays to which the Prizes shall be awarded, and shall declare the name of the successful candidate, or the motto prefixed to his Essay, at the General Meeting of the Society, at which the Prizes shall be awarded. 5. The Committee of the Journal of the Society shall have power to open the motto paper of such Essays, not receiving the Prizes, which they think likely to be useful to the Society, although not obtaining the Prize, and to publish such Essays, as well as the Essay to which the Prize shall be awarded. 6. The copyright of all Essays receiving prizes, shall belong to the Society, who shall have the power to publish the whole or any part of such Essays;

[illegible] always will be returned [illegible] application of the [illegible] Society does not make. [illegible] responsible for their loss. The Society are not bound to award a prize unless in the opinion of the Council of the Society there be merit in the Essays or Experiments the successful claim to be accurately detailed. 9. The Imperial weights and measures only are those by which calculations are to be made. 10. No prize shall be given for any Essay which has been already in print. 11. Prizes may be claimed in money or plate, at the option of the successful candidate. 12. All Essays must be addressed to the Secretary, at the house of the Society.

[By Order of the Council,] JAMES HUDSON, Secretary.

ADDRESS TO THE PLANTERS OF ENGLAND.

TRUE HIGHLAND PINE-TREE.—

MY LORDS, LADIES, AND GENTLEMEN.—The time has [illegible] when all those who [illegible] should plant them. Of this I am fully convinced, and I hope you will allow me to explain on what grounds this opinion is founded. England, generally, is a thickly-wooded country, yet, strange though it may appear, it has not been planted with any view to meet its most urgent wants. If the poor farmer requires an outhouse built for his cattle, he cannot have it because there is no deal-wood in the neighbourhood: he builds it therefore of whins, or of any other rubbish he can lay hold of. Instead of having plenty of fir-wood on all hands to fence young hedges, planted like other things on the common surface of the ground, military-like fortifications have been raised to divide fields, occupying as much good land as is contained in three of the largest counties of Britain: it is on those banks ineffectual attempts have been made to grow hedges. After the 1st of March, when the Royal Agricultural Society's Prizes on fences shall have been awarded, a great proportion of the hedges throughout England will be reconstructed by planting them on the plain surface; and the question will then arise, 'Where is the wood to protect them in their young state to come from?' Turning to the railways which are now being formed in every county in England, another most pressing question arises as to the supply of wood which will be required in their construction. Go up, I am told, to the Highlands of our Island, those immense forests in the north of Scotland—and there how often as many trees will be required.... From these, however, I find we must expect but a limited supply. Like the famous Macedonian, they are already overrun with the axe, and a continuance of the present rate of felling for a few years more will reduce the trees upon them to a mere remnant. If, in fact, the original numbers required for sleepers which will effect this change, besides the incessant demand for timber for purposes that which is already laid down, or may be for the future laid down in additional lines.... So it is, let us see we may, the state of our colonies at the present crisis proves this. Our immense and almost measureless tracts of what is generally called waste land were not created to be a sterile waste merely of unproductive solitude. The rains with which they are refreshed, and the fostering sunshine that rests upon them, might have taught us that Providence had designed them to contribute in some way or other to the wants of man; and though Nature has been unable to lead us to comprehend her lesson, so simply brought before us, necessity has at length compelled us to look to those districts where only a sufficient quantity of timber can be raised to meet our increasing wants. Now, then, is the time to plant; wherever there is a waste piece of ground, moor, or mountain, let it be forthwith invested with trees. For every year, for many years to come, will unquestionably bring with it an additional demand for timber. Thus far on the necessity of planting. Allow me next to bring under notice the sort of tree I would recommend to be planted, which is the chief aim of this Address. That tree is the TRUE HIGHLAND PINE, for introducing which, I had the honour, along with my brother, of receiving the Highland Society's prize. It is admirably fitted, in every respect, to take possession of all the uplands throughout England. It will grow freely on all soils suitable for the common Pine; its wood is very durable; and for railway sleepers it is unrivalled. Brindley, the celebrated engineer, considered its durability equal to that of the Oak; and Dr. Smith states, in the *Transactions of the Highland Society of Scotland*, that he has seen some of it taken down after it had been 300 years in the roof of an old castle, as fresh and full of resin, as newly imported timber from Memel, and that it was actually worked up into new furniture. "Such," says Loudon, "is the durability of this wood, that while the hog timber of the Birch is often found reduced to a pulp, and the Oak cracks into splinters as it dries, the heart of this Pine remains fresh, embalmed in its own turpentine."

MY LORDS, LADIES, AND GENTLEMEN,—Allow me to add a word or two on the merits of this tree as a landscape ornament. In this respect it rivals, if not excels, the Cedar of Lebanon. It has, at any rate, a much better ramification than the Cedar, for, as Sir Walter Scott observes, it assumes in a great measure the bold and contorted figure of the Oak. In illustrating the Seats of Norfolk (and the remark is applicable to all England), it frequently occurred to me that advantage had not been taken of prominent situations by investing them with grand evergreen trees; for so soon as November comes, our parks lose almost all that weight of grandeur for which they are so celebrated in summer-time. Their solemnity ceases with the fall of the leaf; but were they ornamented with this Pine, its broad umbrageous canopy remaining green during winter, the change consequent upon the approach of winter would be much less observed, and our country residences would at all times be surrounded with the dignified accompaniments so consistent with their character.

The importance of this subject will, I doubt not, be accepted as an apology for my thus venturing to express my opinions so plainly on matters of English practice. My suggestion as to the improvement of park and pleasure-ground scenery by introducing the Pine in question is offered with the greatest deference, being fully persuaded that in matters of this description England has been always distinguished for its refined taste. I am ready to dispose of the Highland Pines in the following prices:—

Single Plants, strong and well rooted	6*d.* each.
Strong Plants, 12 to 20 inches high	5*l.* per 100.
Strong Plants, 18 to 18 inches	30*s.* p. 1000.
Small ditto Plants for extensive plantations 10*s.* to	20*s.* p. 1000.

I have the honour to be, My Lords, Ladies, and Gentlemen,

Your most humble Servant,

JAMES GREGOR, Nurseryman, Norwich.

WATERPROOF PATENT CLOTH for COVERING GREEN HOUSES, CUCUMBER or MELON PITS, &c. This Cloth is made expressly for the purpose of applying [illegible] upon, and to which more durable than [illegible] when coated with Dammill's Composition for [illegible] the perfect success of which for many years [illegible] purpose cannot be more fully established than [illegible] the 1st of April last a Black Hamburgh Vine [illegible] Esq., the stem introduced into a house covered [illegible] coated with Composition. On the 1st of Sept. [illegible] a bunch of grapes was cut weighing 16*l.* ounces, the fruit was [illegible] and the flavour pronounced to be excellent. A [illegible] sent again to the Editor of the *Gardeners' Chronicle* [illegible]. The vine grew very luxuriantly, the foliage very fine, and the wood ripened remarkably well. As a winter protection it is infinitely cheaper than glass.

The PATENT CRYSTALLINE COMPOSITION can be obtained of Messrs. Sutton & Middleton, Covent Garden Market; Hunt & Middleton, Goodramgate, York; Wright & Webster, Cornhill; Barclay & Sons, Farringdon Street; and Stanley & Co., Oxford Street. [illegible] Agents, Mr. Bailey, Wolverhampton.

FIRST-RATE PANSIES.—To be Sold, a Bargain, a first-rate Stock of PANSIES, comprising all the best Flowers in cultivation, including some valuable Seedlings not in other hands, together with all Seedlings retained, and three show-boxes of four different sizes; the entire Stock of a most successful Amateur declining their further cultivation. The Pansies are all in small pots, and the Seedlings pricked out in Boxes. For further particulars apply to Mr. W. CHARE, Seedsman, 21, Bishopsgate-street Within, who has on Sale, Cuthill's Unique-thus, 2s. per packet; Cuthill's true Black Spine Cucumber, 2s.; true Cabul Melon, 2s. 6d.; Hoosainee, 2s.; fine mixed Gloxinias, 2s.; Calceolaria, 1s.; Cineraria, 1s.; Tropæolum tricolorum, 2s.; Tropæolum brachyceras, 2s.; warranted Pansy, 2s. 6d.; Joseph Cox, Esq.'s superb Picotee Seed, 5s. May be had on receipt of a Post-office Order.

The Gardeners' Chronicle.

SATURDAY, DECEMBER 7, 1844

MEETINGS FOR THE TWO FOLLOWING WEEKS

Wednesday, Dec 11	Microscopical	7	8 P.M.
Wednesday, Dec 11	Society of Arts	8	8 P.M.
Saturday, Dec 14	Royal Botanic	1	4 P.M.
Tuesday, Dec 17	Linnean	8	8 P.M.

THE probable importance of AUTUMN-PLANTING THE POTATO has been confirmed by an experiment which we had overlooked when speaking of Mr GREY'S. We find that Mr. TROTTER, a gentleman well known in the neighbourhood of Stockton, has been trying the comparative effects of autumn and spring planting on strong clay land, cropped with Beans the previous year. The field was ploughed in November, with a view to its lying in that state through the winter. Mr. Trotter had on former occasions attempted to grow Potatoes on this land; but, from the very strong nature of the soil, it often yielded him little more than the seed he planted This led him to try the effect of planting a piece of ground in the autumn; and accordingly, about a quarter of an acre was re-ploughed about the end of November, manured with stable-yard dung, and planted in the usual way with Yorkshire Red Potatoes, no protection whatever being given them during the winter; a portion of the sets was cut, and another portion planted whole. The plants from the cut sets were much the strongest, and kept a head of the others until the whole of the ground was nearly covered Indeed, Mr. Trotter says that the plants from the cut sets were so much stronger than those from the whole Potatoes, that they could be distinguished with ease at a good distance.

A ridge of land close by the side of that planted in autumn was prepared and planted in spring, and manured in the same way. It is scarcely possible to imagine the difference that existed between the autumn and spring-planted crops. When our informant, Mr G. Watson, gardener at Norton Vicarage, saw them, which was in the second week of October, those which had been planted in autumn were still strong, healthy, and green; while the haulm of those planted in spring was brown, and much withered.

When the crop was taken up, the quarter of an acre planted in autumn yielded 80 bushels of Potatoes; while those planted in spring produced little more than the seed. Mr. Trotter is, we understand, of opinion that on the land planted in autumn there was four times as many Potatoes as on that planted in spring, and that the former were larger and better in quality; and this gentleman has arrived at the conclusion, that for stiff clayey soils it is of the greatest importance to plant in autumn. He was, at the date of our correspondent's letter (Nov. 23), preparing to plant for next year.

At the time of harvesting there was little or no difference between the produce of the cut and uncut sets The Potatoes planted in autumn were only protected by the regular covering of soil; and Mr. Watson finds, upon reference to his journal of the weather, which he keeps in his employer's garden, that the thermometer stood at 16° on the 5th of February, and at 15° on the 6th; this being the greatest amount of frost experienced about Stockton-on-Tees last winter.

Although this experiment was not conducted with the minute exactness characteristic of Mr. Grey's, yet it is valuable as affording additional evidence as to the apparent importance of autumn planting. It also possesses some points of interest of its own.

In the first place, it shows that heavy land is as well suited to autumn planting as light land. We do not mean to say that clay suits Potatoes as well as sandy loam; but that, if heavy land is to be cropped with this plant at all, autumn is the more advantageous season to do it in. It is true that 320 bushels an acre, which was Mr. Trotter's crop, is no great amount of produce; but it is to be borne in mind that the spring-planted crop yielded almost nothing.

Another, and very important fact, elicited by this communication is, that it confirms the correctness of the opinion we last week ventured to express, that it is immaterial at what time before winter the Potato crop is got into the ground. Mr. Trotter's were planted on heavy clay, at the end of November; and, however, uncertain by another season how far this plan can be followed safely; for we have ourselves planted, at the time when these remarks are published, a piece of heavy land, to which no stable manure whatever has been applied.

The last fact that Mr. Trotter's experiment seems to have elicited is, that Potato sets are better than whole tubers. For this we were not prepared; because we should have thought that in heavy land the Potato would have had a better chance of standing the winter when protected by its natural skin, than if cut into pieces. It would, however, appear that even on clay land, in autumn, sets are better than whole Potatoes, as has been so generally found to be the case in the spring, and as was shown by Mr. Grey's experiment on light land.

We wish that those who have the means would now try the experiment of planting Potato sets through every week from the 1st of December till the winter finally sets in. The question would thus be set finally at rest; and we think a more important question can hardly occupy the attention of the cultivators of the soil

Since the above was in type another correspondent has favoured us with his experience of planting Potatoes in the autumn, near Birmingham It appears that in this case the crop was very satisfactory, but no details or comparative statements are given. One thing, however, was observed which deserves mention "The Potatoes, growing at 20 inches deep, and obliged to be got up with the drawing-spade, were so large that some weighed (many) 4 lbs within a few ounces, they decreased in size as they grew nearer the surface, and those at the top, only sufficiently large for the pigs, &c, were very few in proportion"

AN amateur at Nottingham (Mr Thomas Gibson) has been the grower of the heaviest GOOSEBERRY ever recorded as having been exhibited. But it appears that some people are endeavouring to deprive him of the credit he deserves, and publicly assert that heavier berries have been raised. They do not, however, favour us with either the name of the grower, the weight of the fruit they refer to nor the time or place where it was exhibited For ourselves, we have no idea of allowing even a Gooseberry grower to be talked out of his rights, and therefore we have taken some pains to ascertain what the facts are, by searching the records of Gooseberry growing for the last 27 years

The result of this investigation we here produce, with the name, colour, weight, grower's name, and place of exhibition in each case, except for 1829, of which we have no record, and, if we are not mistaken, no lists were published in that year. It will now be found that from 1817 to 1825 no fruit reached 30 dwts; and so also from 1825 to 1830, all were below that standard, until Teazer, a yellow berry, (all the other 26 being reds) reached 32 dwts Nobody again produced a fruit of 30 dwts till 1838; but it will be seen that from 1840 to 1844, for five consecutive years, the heaviest berries have in all cases been above 31 dwts, and the last, that grown by our friend Mr. Gibson, reached the extraordinary weight of 35 dwts 12 grains. It was exhibited at the Carnation Show of the Nottingham Floral and Horticultural Society of the present year, and we are informed that the members of that Society intend presenting Mr Gibson with a piece of plate, as the grower of "The Champion Berry of England."

A return of the heaviest GOOSEBERRIES that have been publicly exhibited between the years 1817 and 1844, both inclusive —

HINTS ON RENOVATING OLD AND LONG NEGLECTED COPPICES.

THE chief object to be attained in improving old neglected coppices is, of course, that the ground should be uniformly covered with stools or stems, as even in size and strength as possible, so as to produce a regular and even crop of wood; this applies more particularly to coppices in Hop districts, where the production of Hop-poles is the primary consideration.

About five years ago I undertook the management, among others, of a large coppice, consisting principally of Alder, Ash, and Red Withy. The stools were of [illegible] of them measuring 3 ft from the ground to the [illegible] had been so long neglected, that the wood [illegible] stools had killed the lesser and weaker ones by overtopping them. The coppice had evidently been originally planted alternately with Alder, Ash, and Withy, but the [illegible] had nearly overpowered their weaker neighbours, the Withy, and appropriated to themselves the whole [illegible] and at the time I took it in hand, there was evidently a struggling for the mastery between the Alder and Ash, and from the weakened appearance of many of the Ash-stools, I have no doubt but that the former (the least deserving) would eventually have been left the sole occupier. I commenced by levering all that I could possibly get from the Ash, and from the few Withy-stems which were found here and there, rejecting the Alder, unless there was no other sort in the vicinity, and in many places I planted very strong plants of Withy, about 6 ft. high, which I trust will ultimately supersede the Alder. The strong high stems of Alder I caused to be lowered a foot, thereby weakening them for a time; but they soon rallied, and progressed at such a rapid rate, that it was evident they would very soon have outstriped the Withy layers and plants, and have regained their former position. In going over the coppice the second season after cutting, I found the Withy layers doing remarkably well, I then had two or three of the large leading shoots of both Ash and Alder taken from the old stools, thus producing a greater uniformity of growth, and giving the weaker-growing sorts a chance of competing with their more powerful neighbours.

In forming coppices I should certainly abstain from planting fast and slow-growing sorts indiscriminately. In many situations the Ash and Alder might be planted together with success; but the latter is of little use except for burning into charcoal for the powder-mill. The Ash will flourish in both wet and dry soils, and when properly managed will produce a vast quantity of marketable produce, and if we take into consideration their rapid growth and the durability of the converted wood, I think we may safely pronounce it to be the most profitable sort we can plant for underwood. The Water Withy (Salix aquatica), will oftentimes successfully compete with the Ash, and even the Alder in growth, if planted in moist situations; but the wood is little, if at all, superior to the Alder for durability. The Red Withy (Salix rubra), is a slow grower, but amply repays any trouble and expense incurred in bringing it to maturity. —*Quercus II.*

ROSE GARDEN.—No. XXI.

(*Continued from page 792.*)

IT must be observed, that directions in horticulture must depend more or less upon the state of the weather. The climate in England is so changeable as to make it impossible to mark, with anything like precision, the most advantageous time for out-of-door operations; and a hard frost succeeding fine weather, which has induced the operator to commence his work, will delay if not defeat his hopes, without a remedy, even where great care has been bestowed to secure success

In grafting, the question seems to be how forward the tree is to be permitted to advance before the scions are inserted. It would seem to be difficult to hit the nice point between putting in the scions before the tree has sap enough to effect a junction and prevent them from suffering, and inserting them so late as to cause a material check in the action of the tree. But the fact is, that the sap is on the rise long before any great exhibition of its effect appears, and if a shoot of the wild Rose be deprived of its head in November, the rise of the sap may be seen in March, by the swelling of the stock before the side shoots, or rather their precursors, the buds, appear to feel it. Stocks which have carried the same heads through the winter show the rise of the sap by the swelling and starting of the buds upon them, while others which have been decapitated in spring, and appear comparatively at rest, will be found, on examination, to be in the same state. The main stem is better to graft upon than the shoots, first, because it makes a handsome tree, secondly, because the bark of the shoot not being so thick as that of the stem, is more likely to get dry and hard: thirdly, because dormant and almost imperceptible buds on the shoots, frequently break out in the clay absorb the sap, and injure the scion, whereas in the stem the bud that appears may be cleft through, and the scion put in its place, perhaps also the vessels in the stem are larger, and the plant required to come in contact can be made to do so with greater facility; and lastly, the sap, rising in a grafted stock, is spread over a larger surface (and the effect of it consequently diminished) when shoots are used, than when the stem is cleft for that purpose. The united circumference of three shoots, or even two if they are vigorous, being more than that of the stem. The difference in labour is also greatly in favour of using the stem, which will receive three or four scions, requiring but one operation in cementing and claying, whereas the use of the shoot involves three times the attention.

From the 1st of March until the stocks get so forward

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

LANE.—ANNUAL COUNTY MEETING, 1846, to be held at SHREWSBURY, in the North Wales District, comprising the Counties of Anglesey, Carnarvon, Merioneth, Montgomery, Denbigh, Flint, Chester, Salop, and Stafford. The Prizes are open to general competition. Forms of Certificate to be procured on application to the Secretary, 12, Hanover-square, London. All Certificates for Entitlements must be returned, filled up, to the Secretary, on or before the 1st of May, and all other Certificates by the 1st of June, the Council having decided that in no case whatever shall any Certificate be received after those dates respectively.

PRIZES FOR THE BREED OF CATTLE.—1846

Short-horns.—CLASS 1. To the owner of the best Bull calved previously to the 1st of January, 1843, 30*l*.; to the owner of the second best do. do. 15*l*.—2. To the owner of the best Bull calved since the 1st of January, 1843, and more than one year old, 20*l*.—3. To the owner of the best Cow in milk or in calf, 15*l*. (In case of the Cow being in calf and not in milk, the Prize will not be given until she is certified to have produced a calf.)—4. To the owner of the best in calf Heifer, not exceeding three years old, 15*l*.—5. To the owner of the best Yearling Heifer, 10*l*.—6. To the owner of the best Bull calf, not exceeding one year old, 10*l*.

Herefords.—CLASS 1. To the owner of the best Bull calved previously to the 1st of January, 1843, 30*l*.; to the owner of the second best do. do., 15*l*.—2. To the owner of the best Bull calved since the 1st of January, 1843, and more than one year old, 20*l*.—3. To the owner of the best Cow in milk or in calf, 15*l*. (In case of the cow being in calf, and not in milk the Prize will not be given until she is certified to have produced a calf.)—4. To the owner of the best in-calf Heifer, not exceeding three years old, 10*l*.—5. To the owner of the best Yearling Heifer, 10*l*.—6. To the owner of the best Bull calf, not exceeding one year old, 10*l*.

Devons.—CLASS 1. To the owner of the best Bull calved previously to the 1st of January, 1843, 30*l*.; to the owner of the second best do. do., 15*l*.—2. To the owner of the best Bull calved since the 1st of January, 1843, and more than one year old, 20*l*.—3. To the owner of the best Cow in milk or in calf, 15*l*. (In the case of the Cow being in calf, and not in milk, the Prize will not be given until she is certified to have produced a calf.)—4. To the owner of the best in-calf Heifer, not exceeding three years old, 10*l*.—5. To the owner of the best Yearling Heifer, 10*l*.—6. To the owner of the best Bull calf, not exceeding one year old, 10*l*.

Cattle of any Breed (not qualified to compete in the foregoing classes).—CLASS 1. To the owner of the best Bull calved previously to the 1st of January, 1843, 20*l*.; to the owner of the second best ditto, 10*l*.—2. To the owner of the best Bull calved since the 1st of January, 1843, and more than one year old, 15*l*.—3. To the owner of the best Cow in milk or in calf, 15*l*. (In the case of the cow being in calf, and not in milk, the prize will not be given until she is certified to have produced a calf.)—4. To the owner of the best in calf Heifer not exceeding three years old, 10*l*.—5. To the owner of the best Yearling Heifer, 10*l*.

HORSES

CLASS 1. To the owner of the best Stallion for Agricultural Purposes, of any age, 30*l*.; to the owner of the second best do. do., 15*l*.—2. To the owner of the best three years old do., 15*l*.—3. To the owner of the best two years old do., 15*l*.—4. To the owner of the best Mare and Foal for Agricultural Purposes, 20*l*.; to the owner of the second best do. 10*l*.—5. To the owner of the best two years old Filly 10*l*.—6. To the owner of the best Thorough bred Stallion, which shall have served mares at a price not exceeding 3 guineas (and with a groom a fee of not more than 6*s*.) in the season of 1845, 30*l*.

SHEEP

PRIZES FOR IMPROVING THE BREED OF SHEEP.—1846

Leicesters.—CLASS 1. To the owner of the best Shearling Ram, 20*l*.; to the owner of the second best do. 15*l*.—2. To the owner of the best Ram of any other age, 20*l*.; to the owner of the second best do., 15*l*.—3. To the owner of the best pen of five Shearling Ewes, 10*l*.; to the owner of the second best do., 5*l*.

Long Woolled Sheep (Not qualified to compete as Leicesters).—CLASS 1. To the owner of the best Shearling Ram, 10*l*.; to the owner of the second best do., 15*l*.—2. To the owner of the best Ram of any other age, 10*l*.; to the owner of the second best do., 15*l*.—3. To the owner of the best pen of five Shearling Ewes, 10*l*., to the owner of the second best do. 5*l*.

Sheep best adapted to a Mountain District.—CLASS 1. To the owner of the best Ram of any age, 15*l*.; to the owner of the second best do., 10*l*., to the owner of the third best do., 5*l*.—2. To the owner of the best pen of Ewes of any age, 10*l*.; to the owner of the second best do., 5*l*.

PIGS

CLASS 1. To the owner of the best Boar of a large breed, 10*l*.; to the owner of the second best do. do., 5*l*.—2. To the owner of the best Boar of a small breed, 10*l*.; to the owner of the second best do., 5*l*.—3. To the owner of the best breeding Sow of a large breed, 10*l*.—4. To the owner of the best breeding Sow, of a small breed, 10*l*.—5. To the owner of the best pen of three breeding Sow pigs of the same litter, above four and under ten months old, 10*l*.

AGRICULTURAL IMPLEMENTS.

A sum not exceeding 50*l*.

Cheese.—To the exhibitor of the best sort of Cheese (of any kind) made within the district, 10*l*. To the exhibitor of the second best do., 5*l*.

Extra Stock, Roots, and Seeds.—For Extra Stock of any kind not shown for any of the previous Prizes, and for Roots Seeds, &c., Prizes may be awarded, if recommended, by the Committee and Judges, to an amount not exceeding in the whole 50*l*.

Any New Implement.—For the invention of any new Agricultural Implement, such sum as the Council may think proper to award.

Steel Wheat, Barley, and Oats.—Ten Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 12 bushels of Wheat of the harvest of 1845, and grown by himself.

II. Fifteen Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 12 bushels of spring Wheat, of the harvest of 1845, and grown by himself.

III. Ten Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 12 bushels of Barley for malting, of the harvest of 1845, and grown by himself.

IV. Ten Sovereigns, or a Piece of Plate of that value, will be given to the exhibitor at the Meeting at Shrewsbury of the best 12 bushels of Oats, of the harvest of 1845, and grown by himself.

Competitors are requested to send with their Wheat, Barley, or Oats, specimens, fairly taken, of the ears in the sack, with the whole of the straw, to a length not less than one foot in diameter, and with the roots attached.

The bushels of the Wheat, Barley, or Oats, will be sealed up by the Director or Secretary, and one of the remaining bushels of each variety will be exhibited, as a sample to the public, the other being kept for comparison with the produce of the next year. At the General Meeting in December, 1846, the Prizes will be awarded.]

The two best samples of each of those classes of Wheat, Barley, or Oats, without reference to the district in which grown, in all of the cases, between the Counties of Hereford and Montgomery, will be selected by the Judges appointed for the Meeting at Shrewsbury; and will be sown, under the direction of the Council (the winter Wheats in the autumn of 1845, and the spring Wheat not earlier than the 1st of March, 1846), by four farmers, who will make their report, upon which the Prizes will be awarded, provided there be such difference between the samples [*illegible*] will be given to the [*illegible*] necessary to each exhibitor whose [*illegible*] for the Barley or Oats.

*** No variety which has been exhibited for [*illegible*] previous Show shall be qualified to compete in the same [*illegible*].

ESSAYS AND REPORTS ON VARIOUS SUBJECTS.

1. *Farming of Nottinghamshire.*—Fifty Sovereigns, or a Piece of Plate of that value, will be given for the best Report on the Farming of the County of Nottingham. Competitors will be expected to describe the different varieties of soil which prevail in the county, the ordinary modes of farming and courses of cropping adopted accordingly in its various districts, and to state how far any peculiar practices in its husbandry are or are not justified by peculiarities of soil or climate. They will also be expected to state what improvements have been made in the farming of Nottinghamshire since the Report of Mr. Robert Lowe in the year 1798; and especially to point out what farther improvements ought to be effected, either by better farming on land already cultivated or by taking new land into cultivation.

2. *Farming of Cornwall.*—Fifty Sovereigns, or a Piece of Plate of that value, will be given for the best Report on the Farming of the County of Cornwall. Competitors will be expected to describe the different varieties of soil which prevail in the county, the ordinary modes of farming and courses of cropping adopted accordingly in its various districts, and to state how far any peculiar practices in its husbandry are or are not justified by peculiarities of soil or climate. They will also be expected to state what improvements have been made in the farming of Cornwall since the Report of Mr. C. S. Worgan, in the year 1811; and especially to point out what farther improvements ought to be effected, either by better farming on land already cultivated or by taking new land into cultivation.

3. *Farming of Kent.*—Fifty Sovereigns or a Piece of Plate of that value, will be given for the best Report on the Farming of the County of Kent. Competitors will be expected to describe the different varieties of soil which prevail in the county, the ordinary modes of farming and courses of cropping adopted accordingly in its various districts, and to state how far any peculiar practices in its husbandry are or are not justified by peculiarities of soil or climate. They will also be expected to state what improvements have been made in the farming of Kent since the Report of Mr. John Boys, in 1796; and especially to point out what farther improvements ought to be effected either by better farming on land already cultivated, or by taking new land into cultivation.

4. *Heath Land.*—Twenty sovereigns, or a piece of plate of that value will be given for an accurate account of the best method of reclaiming heath-land. Competitors will be required to describe methods which have been successfully adopted in the reclaiming of heath land, reference being had especially to the following points.—1. The mode of breaking up, whether by paring and burning, or by simple ploughing. 2. The application of lime. 3. The course of cropping. 4. The conversion of heath-land into pasture, where either the steepness of the land, or its elevation above the sea, does not allow the culture of corn.

5. *Odd Horse Carts.*—Ten Sovereigns or a Piece of Plate of that value will be given for the best Essay on the advantages of One horse Carts. Competitors will be required to point out the saving in horse labour, and other advantages which are doubtedly arise from substituting 1 horse carts for waggons.

6. *Catch Meadows.*—Twenty Sovereigns, or a Piece of Plate of that value will be given for the best Essay on Catch Meadows. Competitors will be required to describe the best and cheapest method of forming water meadows on the sides of natural slopes as practised in Somersetshire and Devonshire; the mode of managing them and of applying their produce; the increase of value thereby given to unproductive hill-sides; and to state how far this mode of improvement might be applied to the mountainous districts of Wales and the North of England.

7. *Fences.*—Twenty Sovereigns or a Piece of Plate of that value, will be given for the best Essay on Fences. Competitors will be required to describe the best and neatest methods of maintaining hedges whether for arable or for grazing ground; and to point out how far the present fences in various parts of England are injurious to the farmer, whether by their size, their excess in number, or the over abundance of timber which they contain.

8. *Fattening Cattle.*—Ten Sovereigns, or a Piece of Plate of that value will be given for an account of the best method of fattening cattle; as to the places in which they are kept, large or small yards or stalls, as well as the food, roots, hay, &c. on which they are fed during the time of fattening.

9. *Tile-yards.*—Twenty Sovereigns, or a Piece of Plate of that value, will be given for the cheapest and best method of establishing a Tile-yard. Competitors will be required to attend to the following points.—1. Mode of working the clay, ascertaining its quality. 2. Machine for making the tiles. 3. Sheds for drying the tiles. 4. Construction of the kiln. 5. Cost of forming the establishment. 6. Cost of the tiles when ready for sale.

10. *Curing Butter.*—Fifty Sovereigns, or a Piece of Plate of that value will be given for the best description of the Dutch method of salting butter, pointing out the causes of its superiority to other salted butters.

11. *Experiment in Agriculture.*—Twenty Sovereigns, or a Piece of Plate of that value, will be given for an account of the best Experiment in Agriculture.

These Essays must be sent to the Secretary, at 12, Hanover square, London, on or before March 1st, 1846.

Twenty Sovereigns or a Piece of Plate of that value, offered by the Right Hon. Lord Kenyon, will be given at the Annual Country Meeting of the Royal Agricultural Society, to be held at Shrewsbury in 1846, for the best Augment of the Use of Gorse for the Food of Cattle, Horses, or Sheep, founded on actual experiment. Competitors will be required to state the following points.—1. The quality of land on which the Gorse is grown. 2. The age of the plant when cut. 3. The mode and expense of cutting. 4. The mode and expense of preparing for food. 5. The method of feeding with Gorse, and the quantity of other food given therewith.

Essays competing for this Prize must be sent to the Secretary, at 12, Hanover-square, on or before May 1, 1846.

Rules of Competition for Prize Essays.—1. All information contained in the Essays shall be founded on experiments or observation, and not on simple reference to books, or other sources. 2. Drawings, specimens, or models (drawn or framed, executed to a scale), shall accompany whatever Essay may require it. 3. All competitors shall [*illegible*] their Essays, and [*illegible*] to cover, on which only their motto, and the subject of the Essay, and the number of that subject to the Prize to which they severally, shall be written. 4. The President of the Society, [*illegible*] for the time being, shall open the cover on which the motto corresponding the Essay to which the Prize has been awarded is written, and shall declare the name of the [*illegible*]. 5. The Transactions of the Journal of the Society shall be the property of the Society, which shall have the power to publish the whole or any part of such Essays; and the other Essays will be returned on the application of the writers, but the Society do not make themselves responsible for their loss. 6. The Society are not bound to award a prize unless they consider one of the Essays deserving of it. 7. In all reports of experiments the expenses shall be accurately detailed. 8. The imperial weights and measures only are those by which calculations are to be made. 10. No prize shall be given for any Essay which has been already in print. 11. Prizes may be taken in money or plate, at the option of the successful candidate. 12. All Essays must be addressed to the Secretary, at the house of the Society.

(By Order of the Council.) JAMES HUDSON, Secretary.

ADDRESS TO THE PLANTERS OF ENGLAND.

TRUE HIGHLAND PINE-TREE.

MY LORDS, LADIES, AND GENTLEMEN.—The time has been when all those who have waste land at their disposal should plant them. Of this I am fully persuaded, and I beg you will allow me to explain on what principles this is founded. England, generally, is a thickly-wooded country, yet, strange though it may appear, it has not been planted with any view to meet its most urgent wants. If the poor farmer require an outhouse built for his cattle, he cannot have it because there is no dead-wood in the neighbourhood; he builds it therefore of straw, or of any other rubbish he can lay hold of. Instead of having plenty of fir wood on all hands to fence young hedges, planted like other things on the common surface of the ground, military-like fortifications have been raised to divide fields occupying as much good land as is contained in three of the largest cheshire of Britain. It is on these banks ineffectual attempts have been made to grow hedges. After the 1st of March, when the Royal Agricultural Society's Prize on fences shall have been awarded, a great proportion of the hedges throughout England will be reconstructed by planting them on the plain surface; and the question will then arise, "Where is the wood to protect them in their young state to come from?" Turning to the railways which are now being formed in every county in England, another and greater question arises as to the supply of wood which will be required in their construction. Go up, I am told, to the Lebanons of our island—those immense forests in the north of Scotland—and there how down as many trees as will be required. From those, however, I find we must expect but a limited supply. Like the famous Mount Seguid, they are already overrun with the axe, and a continuance of the present rate of cutting for a few years more will reduce the trees upon them to a mere remnant. It is not the original numbers required for sleepers which will effect this change, but it is the incessant demand, *ad infinitum*, for timber to replace that which is already laid down, or may be for the future laid down in additional lines. Look at it how we may, the state of our country at the present even prov a state not immense and almost uncultivated tracts of what is generally called waste land were not created to be a scene merely of unproductive solitude. The rains with which trees are refreshed and the fostering sunshine that rests upon them, might have taught us that Providence had designed them to contribute in some way or other to the wants of man; and though Nature has been unable to lead us to comprehend her lessons, so simply brought before us, necessity has at length compelled us to look to those districts where only a sufficient quantity of timber can be raised to meet our increasing wants. Now, then, is the time to plant wherever there is a waste piece of ground, moor, or mountain, let it be forthwith invested with trees, for every year, for many years to come, will unquestionably bring with it an additional demand for timber. Thus far on the necessity of planting. Allow me next to bring under notice the sort of tree I would recommend to be planted, which is the chief aim of this Address. That tree is the TRUE HIGHLAND PINE, for introducing which, I had the honour, along with my brother, of receiving the Highland Society's prize. It is admirably fitted, in every respect, to take possession of all the uplands throughout England. It will grow freely on all soils suitable for the common Pine; its wood is very durable; and for railway sleepers it is unrivalled. Brindley, the celebrated engineer, considered its durability equal to that of the Oak, and Dr Smith states, in the *Transactions of the Highland Society of Scotland*, that he has seen some of it taken down after it had been 250 years in the roof of an old castle, as fresh and full of resin, as newly imported timber from Memel, and that it will actually worked up into new furniture. "Such," says Loudon, "is the durability of this wood, that while the hog timber of the Birch is often found reduced to a pulp, and the Oak cracks into splinters as it dries, the heart of this Pine remains fresh, embalmed in its own turpentine."

MY LORDS, LADIES, AND GENTLEMEN.—Allow me to add a word or two on the merits of this tree as a landscape ornament. In this respect it rivals, if not excels, the Cedar of Lebanon. It has, at any rate, a much better ramification than the Cedar, for, as Sir Walter Scott observes, it assumes in a great measure the bold and contorted figure of the Oak. In illustrating the Seats of Norfolk (and the remark is applicable to all England), it frequently occurred to me that advantage had not been taken of prominent situations by investing them with grand evergreen trees, for no soon as November comes, our parks lose almost all that weight of grandeur for which they are so celebrated in summer time. Their solemnity ceases with the fall of the leaf; but were they ornamented with this Pine, its broad umbrageous canopy remaining green during winter, the change consequent upon the approach of winter would be much less observed, and our country residences would at all times be surrounded with the dignified accompaniments so consistent with their character.

The importance of this subject will, I doubt not, be accepted as an apology for my thus venturing to express my opinions so plainly on matters of English practice. My suggestion as to the improvement of park and pleasure-ground scenery by introducing the Pine in question is offered with the greatest deference, being fully persuaded that in matters of this description England has been always distinguished for its refined taste. I am ready to dispose of the Highland Pines at the following prices:—

Single Plants, strong and well rooted	6*d* each.
Strong Plants, 18 to 20 inches high	5*s* per 100
Strong Plants, 15 to 18 inches	40*s* p 1000.
Transplanted Plants for exposed situations 10*s*. to 30*s*. p 1000.	

I have the honour to be, My Lords, Ladies, and Gentlemen,

Your most humble Servant,

JAMES GRIGOR, NURSERYMAN, Norwich.

WILLMENT'S PATENT CLOTH for COVERING GARDEN HOUSES, CUCUMBER or MELON PITS, &c. This Cloth is made expressly for the purpose of applying Willment's Composition upon, and is much more durable than any other Material when coated. It is beautifully white and transparent. The perfect success of Willment's Composition for the above-named purposes cannot be more fully established than by the fact, that on the 1st of April last, a Black Hamburgh Vine in a Greenhouse, the glass [illegible] into a house not exceeding 8 feet square, was cut weighing 48*l*. ounces, the fruit was perfectly ripened, and the flavour pronounced to be excellent. A complete description was sent up in the Editor of the *Gardeners' Chronicle* last September. The open summer very luxuriantly, the foliage every fine, and the wood ripened exceedingly well. As a winter protection it is infinitely superior to mats.

The PATENT UNFERMENTED COMPOSITION can be obtained of Messrs. Bailey & Sheasby, Covent Garden Market; Hurst & M'Mullen, Leadenhall Street; Wargent & Warner, Cornhill; Barclay & Sons, Farringdon Street; and Chaunay & Co., Oxford Street.—Wholesale and Shipping Agents, Messrs. Bailey, Wolverhampton.

FIRST-RATE BUSINESS.—To be Sold, a Bargain, a first-rate Stock of PENDENT, comprising all the most forward as cultivators, including some valuable Seedlings not in other hands, together with all Seedlings worth a placement, and allow house of four different sizes; the entire Stock of a most successful Amateur declining their further cultivation. The Pendents are all in small pots, and the Seedlings pricked out in boxes. For further particulars apply to Mr. W. CLARK, Seedsman, 70, Bishopsgate-street Within, who has on Sale, Cuthill's Lasting Stock, 3s. per paper; Cuthill's true Black Spine Cucumber, 2s.; true Cabul Melon, 2s. 6d.; Roccalnea, 2s.; fine mixed Gloxinias, 1s.; Calceolaria, 1s.; Cinerarie, 1s.; Tropeolum tricolorum, 2s.; Tropeolum brachyceras, 2s.; warranted Pansy, 2s. 6d.; Joseph Cox, Esq.'s superb Ricotee Seed, 2s. May be had for Remittance of a Post-office Order.

The Gardeners' Chronicle.

SATURDAY, DECEMBER 7, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

WEDNESDAY Dec. 11	Meteorological	8 P.M.
WEDNESDAY Dec. 11	Society of Arts	8 P.M.
SATURDAY, Dec. 14	Royal Botanic	4 P.M.
TUESDAY, Dec. 17	Linnean	8 P.M.

THE probable importance of AUTUMN-PLANTING THE POTATO has been confirmed by an experiment which we had overlooked when speaking of Mr. GREY'S. We find that Mr. TROTTER, a gentleman well known in the neighbourhood of Stockton, has been trying the comparative effects of autumn and spring planting on strong clay land, cropped with Beans the previous year. The field was ploughed in November, with a view to its lying in that state through the winter. Mr. Trotter had on former occasions attempted to grow Potatoes on this land; but, from the very strong nature of the soil, it often yielded him little more than the seed he planted. This led him to try the effect of planting a piece of ground in the autumn; and accordingly, about a quarter of an acre was re-ploughed about the end of November, manured with stable-yard dung, and planted in the usual way with Yorkshire Red Potatoes, no protection whatever being given them during the winter; a portion of the sets was cut, and another portion planted whole. The plants from the cut sets were much the strongest, and kept a-head of the others until the whole of the ground was nearly covered. Indeed, Mr. Trotter says that the plants from the cut sets were so much stronger than those from the whole Potatoes, that they could be distinguished with ease at a good distance.

A ridge of land close by the side of that planted in autumn was prepared and planted in spring, and manured in the same way. It is scarcely possible to imagine the difference that existed between the autumn and spring-planted crops. When our informant, Mr. G. Watson, gardener at Norton Vicarage, saw them, which was in the second week of October, those which had been planted in autumn were still strong, healthy, and green; while the haulm of those planted in spring was brown, and much withered.

When the crop was taken up, the quarter of an acre planted in autumn yielded 60 bushels of Potatoes; while those planted in spring produced little more than the seed. Mr. Trotter is, we understand, of opinion that on the land planted in autumn there was four times as many Potatoes as on that planted in spring, and that the former were larger and better in quality; and this gentleman has arrived at the conclusion, that for stiff clayey soils it is of the greatest importance to plant in autumn. He was, at the date of our correspondent's letter (Nov. 25), preparing to plant for next year.

At the time of harvesting there was little or no difference between the produce of the cut and uncut sets. The Potatoes planted in autumn were only protected by the regular covering of soil; and Mr. Watson finds, upon reference to his journal of the weather, which he keeps in his employer's garden, that the thermometer stood at 16° on the 5th of February, and at 15° on the 6th; this being the greatest amount of frost experienced about Stockton-on-Tees last winter.

Although this experiment was not conducted with the minute exactness characteristic of Mr. Grey's, yet it is valuable as affording additional evidence as to the apparent advantages of autumn planting. It also possesses some points of interest of its own.

In the first place, it shows that heavy land is as well suited to autumn planting as light land. We do not mean to say that clay suits Potatoes as well as sandy loam; but that, if heavy land is to be cropped with this plant at all, autumn is the more advantageous season to do it in. It is true that 320 bushels an acre, which was Mr. Trotter's crop, is no great amount of produce; but it is to be borne in mind that the spring-planted crop yielded almost nothing.

Another, and very important, fact, elicited by this communication is, that it confirms the correctness of the opinion we last week ventured to express, that it is immaterial at what time before winter the Potato crop is got into the ground. Mr. Trotter [illegible] planted on [illegible] clay, at the end of November. We shall, however, ascertain by another season how far this point can be followed safely; for we have ourselves planted, at the time when these remarks are published, a piece of heavy land, to which no stable manure whatever has been applied.

The last fact that Mr. Trotter's experiment seems to have elicited is, that Potato sets are better than whole tubers. For this we were not prepared; because we should have thought that in heavy land the Potato would have had a better chance of standing the winter when protected by its natural skin, than if cut into pieces. It would, however, appear that even on clay land, in autumn, sets are better than whole Potatoes, as has been so generally found to be the case in the spring, and as was shown by Mr. Grey's experiment on light land.

We wish that those who have the means would now try the experiment of planting Potato sets through every week from the 1st of December till the winter finally sets in. The question would thus be set finally at rest; and we think a more important question can hardly occupy the attention of the cultivators of the soil.

Since the above was in type another correspondent has favoured us with his experience of planting Potatoes in the autumn, near Birmingham. It appears that in this case the crop was very satisfactory; but no details or comparative statements are given. One thing, however, was observed which deserves mention. "The Potatoes, growing at 20 inches deep, and obliged to be got up with the draining-spade, were so large that some weighed (many) 4 lbs. within a few ounces; they decreased in size as they grew nearer the surface, and those at the top, only sufficiently large for the pigs, &c., were very few in proportion."

AN amateur at Nottingham (Mr. Thomas Gibson) has been the grower of the heaviest GOOSEBERRY ever recorded as having been exhibited. But it appears that some people are endeavouring to deprive him of the credit he deserves, and publicly assert that heavier berries have been raised. They do not, however, favour us with either the name of the grower, the weight of the fruit they refer to, nor the time or place where it was exhibited. For ourselves, we have no idea of allowing even a Gooseberry grower to be talked out of his rights; and therefore we have taken some pains to ascertain what the facts are, by searching the records of Gooseberry-growing for the *last* 27 years.

The result of this investigation we here produce, with the name, colour, weight, grower's name, and place of exhibition in each case, except for 1829, of which we have no record; and, if we are not mistaken, no lists were published in that year. It will now be found that from 1817 to 1825 no fruit reached 30 dwts.; and so also from 1825 to 1830, all were below that standard, until Teazer, a yellow berry, (all the other 26 being reds) reached 32 dwts. Nobody again produced a fruit of 30 dwts. till 1838; but it will be seen that from 1840 to 1844, for five consecutive years, the heaviest berries have in all cases been above 31 dwts., and the last, that grown by our friend Mr. Gibson, reached the extraordinary weight of 35 dwts. 12 grains. It was exhibited at the Carnation Show of the Nottingham Floral and Horticultural Society of the present year, and we are informed that the members of that Society intend presenting Mr. Gibson with a piece of plate, as the grower of "The Champion Berry of England."

A return of the heaviest GOOSEBERRIES that have been publicly exhibited between the years 1817 and 1844, both inclusive:—

HINTS ON RENOVATING OLD AND LONG NEGLECTED COPPICES.

THE chief object to be attained in improving old neglected coppices is, of course, that the ground should be uniformly covered with stools or stems, as even in size and strength as possible, so as to produce a regular and even crop of wood; this applies more particularly to coppices in Hop districts, where the production of Hop-poles is the primary consideration.

About five years ago I undertook the management, among others, of a large coppice, consisting principally of Alder, Ash, and Red Withy. The stools were of large size, many of them measuring 3 ft. from the ground to the [illegible] and had been so long neglected, that the wood [illegible] had killed the lesser and weaker ones [illegible]. The coppice had evidently been [illegible] alternately with Alder, Ash, and Withy, but the [illegible] had nearly overpowered their weaker neighbours, the Withy, and appropriated to themselves the whole [illegible], and at the time I took it in hand, there was evidently a struggling for the mastery between the Alder and Ash, and from the weakened appearance of many of the Ash-stools, I have no doubt but that the former (the least deserving) would eventually have been left the sole occupier. I was induced by layering all that I could possibly get from the Ash, and from the few Withy-stems which were found here and there, rejecting the Alder, unless there was no other sort in the vicinity, and in many places I planted very strong plants of Withy, about 6 ft. high, which I trust will ultimately supersede the Alder. The strong high stems of Alder I caused to be lowered a foot, thereby weakening them for a time; but they soon rallied, and progressed at such a rapid rate, that it was evident they would very soon have outstriped the Withy layers and plants, and have regained their former position. In going over the coppice the second season after cutting, I found the Withy layers doing remarkably well; I then had two or three of the large leading shoots of both Ash and Alder taken from the old stools, thus producing a greater uniformity of growth, and giving the weaker-growing sorts a chance of competing with their more powerful neighbours.

In forming coppices I should certainly abstain from planting fast and slow-growing sorts indiscriminately. In many situations the Ash and Alder might be planted together with success; but the latter is of little use except for burning into charcoal for the powder-mill. The Ash will flourish in both wet and dry soils, and when properly managed will produce a vast quantity of marketable produce; and if we take into consideration their rapid growth and the durability of the converted wood, I think we may safely pronounce it to be the most profitable sort we can plant for underwood. The Water Withy (Salix aquatica), will oftentimes successfully compete with the Ash, and even the Alder in growth, if planted in moist situations; but the wood is little, if at all, superior to the Alder for durability. The Red Withy (Salix rubra), is a slow grower, but amply repays any trouble and expense incurred in bringing it to maturity. —*Quercus II.*

ROSE GARDEN.—No. XXI.

(*Continued from page 732.*)

IT must be observed, that directions in horticulture must depend more or less upon the state of the weather. The climate in England is so changeable as to make it impossible to mark, with anything like precision, the most advantageous time for out-of-door operations; and a hard frost succeeding fine weather, which has induced the operator to commence his work, will delay if not defeat his hopes, without a remedy, even where great care has been bestowed to secure success.

In grafting, the question seems to be how forward the tree is to be permitted to advance before the scions are inserted. It would seem to be difficult to hit the nice point between putting in the scions before the tree has sap enough to effect a junction and prevent them from suffering, and inserting them so late as to cause a material check in the action of the tree. But the fact is, that the sap is on the rise long before any great exhibition of its effect appears, and if a shoot of the wild Rose be deprived of its head in November, the rise of the sap may be seen in March, by the swelling of the stock before the side shoots, or rather their precursors, the buds, appear to feel it. Stocks which have carried the same heads through the winter show the rise of the sap by the swelling and starting of the buds upon them, while others which have been decapitated in spring, and appear comparatively at rest, will be found, on examination, to be in the same state. The main stem is better to graft upon than the shoots; first, because it makes a handsome tree; secondly, because the bark of the shoot not being so thick as that of the stem, is more likely to get dry and hard: thirdly, because dormant and almost imperceptible buds on the shoots, frequently break out in the clay, absorb the sap, and injure the scion; whereas in the stem the bud that appears may be cleft through, and the scion put in its place; perhaps also the vessels in the stem are larger, and the plant required to come in contact can be made to do so with greater facility; and lastly, the sap, rising in a grafted stock, is spread over a larger surface (and the effect of it consequently diminished) when shoots are used, than when the stem is cleft for that purpose. The united circumference of three shoots, or even two if they are vigorous, being more than that of the stem. The difference in labour is also greatly in favour of using the stem which will receive three or four scions, requiring but one operation in cementing and tying, whereas the use of the shoot involves three times the attention.

From the 1st of March until the stocks get so forward

as to be injured materially by taking off their heads, the stem of the wild Rose may be successfully grafted, provided the wound be carefully kept from the air; and although (when grafted early in the season) the scion will remain in the stock for months without bursting, as long as the bark and buds remain plump no fear need be entertained. The junction between the scion and stock is so slow that the growth of the buds appears quite imperceptible, but where once a single well expanded leaf is found upon the bud, the scion incorporates with the stem, and the tree, being then in a natural state, vegetates with vigour.

Those who object to use clay may defend their graft with the mixture, swathing the head of the stock and scion in Moss, which must be occasionally wetted with a watering-pot. The success of this method is not quite equal to claying, which moistens the head of the stock, softens the bark, and by facilitating the passage of the sap to the base of the scion, effects a speedy junction. Moss is, however, admirably adapted to preserve scions in vigour until they are connected with the tree; and such buds as are hidden in it will frequently break out with vigour, while that part of the scion which is exposed to the air dies off entirely. To enable the operator to keep his scions moist, it is necessary that all wild buds beneath the ligature be so confined as to render them unable to receive or use the sap which rises in the stock; and if the last bandage be carefully and closely twisted round the stocks and scion, it will admit of the passage of moisture to the bark of such scion, while at the same time it prevents the swelling of the buds of the subject. When an overplus of any valuable sort of scions remain, they may be advantageously used by cutting down the shoots of any stools of Roses about the garden, near to the ground, and cleft-grafting them in the same manner as the wild stock. Their vicinity to the ground, which renders them so little liable to be blown about and injured by the wind, will do away with the necessity of claying, a common sailor's knot being slipped over the heads of each, and tied in front; the mixture No. 3 is applied to the graft, which (as only one scion is entered in a shoot, and but one bud left to break) can be done with the greatest facility, and the shoot produced may be laid down the same season, and be cut off from the stool a perfect and independent plant, upon its own bottom, the same autumn; while the operator is enabled to avail himself of the assistance of a handglass, if required, to advance his layers. Two or three buds of the new shoot should be left upon each graft of the stock for flowering in the ensuing spring.

The inserted scions are greatly helped, until supplied with nourishment from the stock, by the moisture of the clay; if therefore the lowest bud be only a quarter of an inch above the head of the stock, it will remain alive though concealed in the clay, and lie dormant (having no power of breaking out before that time), till the midsummer shoot, when, if the clay be removed, it will grow rapidly. This is a desirable method of finding vent for excess of sap at midsummer, as well as of limiting the demand upon trees in the spring. If this mode be adopted, the clay should be removed and the ligature loosened, when the spring shoot is over; the mixture being then applied in the same manner as to other wounds, the point of the bud only being left free. If there be not vigour enough in the tree to start the bud during the autumn, it will lie dormant, and break out with increased strength the next spring. In many cases, however, the spring shoots alone will increase the size of the scions and head of the stock so much, that it may be necessary to loosen the bandage, which may be done during the month of June, when the tree is usually in a state of comparative rest, between the spring and midsummer shoots. The most favourable time for removing the clay is after rain, when, having become soft, there will be less risk of injuring the scions. If the stem be large and but one scion take, a quantity of dead wood at the head of the stock will be the result; the whole of this must either at this period, or eventually, be cut away and the place defended with the mixture, or the operation of grafting must (as to the Rose) be abandoned.

OPERATIONS IN DIFFERENT MONTHS.

January.—Procure wild stocks, if delayed before.

February.—Wild stocks may still be planted with advantage, but the season is getting forward; cut and put by some scions for grafting; beat up clay for that purpose, and attend to the buds in the wild stocks.

March.—This is the last month to plant wild stocks; prune all trees which were grafted last or budded the year before, and restake those that have got blown about; graft fresh stocks; pinch off wild buds where not wanted, and from those trees which have been budded 18 months cut off the remaining parts of the old stock and that part of the budded shoot which is beyond the bud inserted—the first to the base of the shoot, the second close to the bud; they are then expected nearly to heal over the same year: cover them with cement for that purpose.

April.—Attend to cleft grafts by keeping down the buds below them, eradicating suckers, and cutting off the heads of failing grafts to bud upon in autumn; attend to the shoots budded upon last year; nip off the point of the sap-bud where required, and put on guards; kill snails and caterpillars this month, and whensoever afterwards they can be found; leave some flower-pots inverted to catch slugs in, which will infallibly harbour them; stop newly-starting buds when they have formed three or four eyes, that a head may be formed at once.

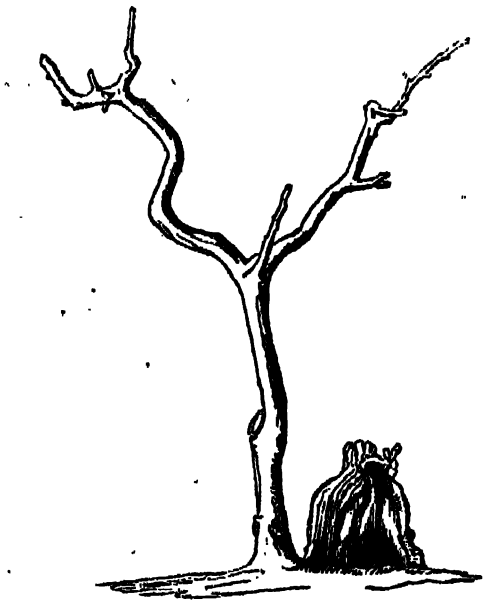
May.—Attend to the buds and suckers of wild stocks, and tie the new shoots to the guards, where necessary, without delay.

June, as in May.

July.—If the season be early, bud at the end of this month.

August.—Bud all this month, and if any buds start, they may be treated as pushing eyes; but, under such circumstances, the whole of the shoots upon the same tree must be shortened, or the curtailing of one shoot would be a mere transfer of its sap to another, to the great detriment, if not eventual death of the inserted bud; attend to ligatures.

September.—Continue to watch all newly inserted buds, and for the first fortnight replace any that fail; loosen the ligatures if necessary, but not without, except to examine where there may be reason to think they require it.



October.—Transplant in the last week; cutting off the ends of the wild branches, as directed.

November.—Take up any trees (carefully examining their roots) it may be desirable to remove, and replant them immediately; procure fresh wild stocks to plant, and set them out in line, or if delayed, lay them by the heels.

December.—The same as last month.

THE ORIGINAL RIBSTONE PIPPIN APPLE-TREE.

The accompanying is a representation of what remains of this renowned tree, with a few observations on its present condition.

The Original Ribstone Pippin Apple-tree.
April 20, 1844.

A small portion of the old trunk, as represented in the above engraving, still exists, and stands about 9 inches from the ground; and out of this, about 4 inches below the surface, springs a branch, which with proper care may yet become a tree. It is about 4 feet in height, and appears to be of about 10 years' growth. It stands in an exposed part of the park, and is merely fenced round with Scotch fencing. The soil in which it grows is of a tolerably free, open texture, on a sandy and gravelly subsoil.

When the tree first came under my care (scarcely two years ago) it was nearly devoured with the woolly aphis and canker, and almost overgrown with Nettles. I had the inclosed area (which is about 6 yards in diameter) thoroughly cleaned, part of the earth removed, a quantity of fresh earth brought in, and some of the roots raised into the fresh soil. I have not been able to accomplish the extirpation of the aphis. I believe their stronghold is in the old stool under the ground; for in spite of all I could do, they still continue to make their appearance on the young branches. I have much satisfaction in observing that the young branches indicate a decided improvement in health and vigour, having now a good broad foliage, and showing no signs of canker. The roots are pushing freely into the fresh earth, and many young roots have sprung from the base of the principal branch or sucker. By encouraging these young roots, keeping them near the surface, and otherwise nursing the shoot, I have no doubt that the old tree may be revived, and as there are already several incipient blossom-buds on the heretofore sickly branches, probably the year 1846 may be remarkable for the reproduction of fruit on the original Ribstone Pippin.

I am informed that the old tree was broken down in the year 1815, after which only one large branch remained, which was supported by stakes in a horisontal position, as shown in the engraving figured below. In this state it bore fruit for many years, and while in this position many layers were taken from it. It lingered until 1835, when it died, and was removed and burnt. The remainder of the trunk, excepting the small portion which now stands, was removed in 1839, and is carefully preserved by Joseph Dent, Esq., the present proprietor of Ribstone.

Although I have hitherto spoken of the old Ribstone Pippin-tree as the original, yet I am of opinion that it had been grafted; and if so, of course it is not the original. My suspicions on this point were first raised by the appearance of a sucker which is growing in the garden at Ribstone, and which was taken from the old tree sixteen or eighteen years ago. This tree has not yet borne fruit: it has thriven badly, being greatly affected by canker: it is now in a more healthy state, and forming many blossom-buds. I could not reconcile the habit of this tree with that of the true Ribstone Pippin, and consequently took considerable pains to ascertain if any and what measures had been taken to prove whether the old tree had been grafted or not. In pursuit of this object various and contradictory was the evidence that I met with. The strongest evidence that I obtained of its being a grafted tree, was from a person whose voluntary testimony I have no reason to doubt, and who positively asserts that he took a root-sucker from the old Ribstone Pippin-tree, and planted it against a wall, where it remained until it bore fruit, which proved to be a bad Crab. The sucker was then destroyed. On the other side, Mr. Thompson, of the Horticultural Society's Garden at Chiswick, informs me that there is growing in that garden a tree which was raised from a sucker that was taken from the original tree at Ribstone with a piece of the old root attached, eighteen years ago, and that this tree has borne fruit identical with the true Ribstone Pippin. However contradictory these accounts may appear, they may nevertheless be both correct; if the old tree has been grafted (admitting this) we must suppose that the tree in the Chiswick Gardens has been raised from an underground branch, which branches frequently put out roots at their bases, and that the old tree has been grafted very low, having the earth about its stem considerably raised; or it may have sprung from the roots of some of the layers, of which there were many before that time.

It is much to be regretted that this point has not been settled beyond dispute, as it ought to have been long ago. This neglect is scarcely to be accounted for, unless we suppose it to be consequent on the many changes which have taken place, or, if it has been proved, the unwillingness to publish the fact. It therefore remains enveloped in mystery, and will probably rest so (unless some of the existing suckers prove the old tree to have been grafted) until a root-sucker is raised from the old stool, which I think is practicable, and which I purposed attempting had I remained at Ribstone.—*James Craig, late Gardener at Ribstone Park.*

Home Correspondence.

Tank-heating.—I have observed, on two or three occasions, that an opinion has been expressed in the *Chronicle* unfavourable to the use of pottery for the construction of tanks and gutters as channels for hot water. On one occasion there was a specific objection, viz., the alleged impossibility of avoiding leakage. I am inclined to think that such objections must have resulted from imperfection in the materials from which the pottery was prepared, in the arrangement of it when made, or in the material used in connecting and cementing the parts together. My houses and pits, of which plans and particulars are given at p. 428, 1844, are heated exclusively by gutters of pottery and tanks of the same mate-

rial, the latter having a brick foundation; they answer entirely to the satisfaction of my gardener and myself. They have now been in constant use for full 12 months, without any alteration, and we discover no leakage in any part. I apprehend that the atmosphere of the houses is somewhat more moist than in those in which iron is employed. The luxuriance and beauty of the foliage and flowers, particularly of Roses in pots, during the whole of last winter, was remarkable. The plants expressed their enjoyment very unequivocally. The Pine plants in the pits have afforded similar evidence of enjoyment throughout the season, bearing a fine dark-green foliage, without a tinted leaf to be seen. My experience, therefore, induces me strongly to recommend the article, as by far the most economical and congenial to healthy vegetation.—*Chas. Lawrence, Cirencester.* [Upon receiving this letter we applied to our kind correspondent for information as to the cement with which the pipes are jointed; it having been found near London impracticable to prevent the joints of pipes set in cement from cracking and leaking. The following is his obliging reply:]—I should suppose that the pottery you have used and mine may be very different in quality and construction. Earthen pipes, such as I have seen, are very porous, and not above half an inch in thickness; whereas, my gutters are made of very tough clay, well ground, and are from 1½ inch thick and upwards; the surface is very smooth and compact for such an article. The man who set my work informs me that the lime used in making the cement in which they were set is "Haberworth lime." Of the name I know nothing; but I believe the article is prepared from burning a sort of pebble found near the sea instead of the ordinary limestone. At all events I understand this to be a lime well known, and commonly employed in works under water; it is said to set better under water than above. The lime I used was obtained from Gloucester. While the work was in hand, I thought the man extremely careless in not grinding the cement in a pug-mill or something of the sort, as I observed indications after the trowel of considerable particles of grit, which I thought would be a source of leakage; but he was so confident as to his material, that I was obliged to let him take his own course, merely telling him I did not believe the work would hold water, and that I would not pay him till it did. The result was a considerable leakage in particular places; he put these to rights, and then, at my desire, put a thin coat of Roman cement over the whole of the interior. (?) The houses were set to work in November, 1843, and have gone on to this time without any leakage. Whether this be due to the Roman cement, or the cement by which the work was first put together, I cannot say. At the points, where I have moveable tops to steam the house, I cannot perceive any disturbance whatever of the internal coating of Roman cement, which would, of course, have cracked with any expansion or contraction of the gutters. I should, however, put my faith rather in the original cement, if I were to go to work again, taking care to have it thoroughly reduced by grinding. My expectation is that my work will stand for ever, barring change accidents, against which it is pretty effectually protected. Any one can see my apparatus who is disposed to take the trouble of a jaunt by the Great Western.—*Charles Lawrence.*

The Bignonia Venusta.—In reply to Mr. Beaton, I beg to give my mode of prolonging the blooming of this useful plant. The situation in which it most delights is a bark-bed, where the roots can run at liberty among the tan. The plant here was first potted in a 16-sized pot, and then placed in a corner of a bark-bed, where Pines are grown; it has occupied that place now for 10 years, and although the bark-bed is regularly turned every year, yet the disturbing of the roots does not injure the plant; the roots being found to run along by the wall that forms one side of the pit, and the end, the heat of the tan preventing them from progressing towards the centre. The plant is trained upright until it reaches the top-lights; it is then trained along the house, which is 35 feet in length and 8 feet in width, till it reaches the other end, covering the pathway at the back of the bark-bed. Towards the end of December, I cut the plant in to 6 or 10 feet, when it remains dormant through the winter, without a leaf upon it, although occupying a warm situation in a fruiting Pine-stove. In the beginning of March, young shoots in abundance break from the apparently dead wood; a sufficient number of these are selected to be trained along the house, and these again produce laterals, about a foot or 2 feet in length; and at the end of each, a cluster of blossom-buds is formed. On the production of those lateral shoots depends the free blooming of the plant, to encourage which, a damp atmosphere is kept by pouring water over the pathways, and by frequently syringing the plant. All superfluous shoots are stopped; and it is necessary to pay a good deal of attention to this, for an over-abundance of shoots would soon be produced that would form a complete thicket. The plant here commences flowering about the beginning of September; it is now in full flower from one end of the house to the other, and has an exceedingly gay appearance.—*James Brown, Gardener to Lord Southampton, Whittlebury Lodge.*

The Golden Pippin.—I am glad to return to this favourite fruit again, because I consider it not unimportant to its disposal or value to be "Gentlefolkish" would have us. Mr. Knight preferred the Gurnish Gillyflower to all other Apples; I prefer the Golden Pippin, and so do many others; on this account its degeneracy is surely worth investigating. I am willing to defer largely to so great an authority as Mr. Knight, but with such proofs as are now received, his doctrine may at least be considered questionable, if not entirely fallacious. It is all very well to talk about originating similar or better kinds; but with the hundred and one attempts to accomplish this, what is the result? Who in our time has succeeded in producing an Apple equal to the Golden Pippin? I am inclined to think it wiser to bear the ills we have, and see whether it is possible to retain this valuable Apple during, at least, our time. That it grows vigorously and produces fine crops of fruit, at Hewel in Worcestershire, is beyond all doubt; the selfsame kind of Apple also, under the eye of Mr. Falconer, has for 20 years done the same thing, and in neither of these instances has the least sign of constitutional debility shown itself. Mr. Knight, in a paper read before the Horticultural Society of London, May 3d, 1831, hinted at the probability of retarding the deterioration of valuable varieties of fruits. If, without Divine intervention, a man could stop the sun in his course for one hour, why not for a thousand? Mr. Falconer has at least shown that he has successfully done it with the Golden Pippin; so has Mr. Markham, and I dare say many others; and with such authority I leave the subject for the present. —*R. G.*

Birch Coppices.—I have planted Birch rather extensively, and in various soils, but more for cover than from any hope of its ever growing into anything better than bavin wood. I cut generally six or seven years after planting, and I invariably find that a great number of the stools die in consequence. I have cut the tree partly through and layered it, and I generally find the same effect produced. If some of your correspondents will have the kindness to point out the cause, they will confer a favour upon—*Romseyonienstis.*

Hybrid Melons.—In answer to "Querist" (p. 782,) I beg to state that I am well acquainted with the Melon called Pitt's Improved Egyptian Greenfleshed; but in my opinion it is wrong named: instead of being called the Improved Egyptian Greenfleshed, it should be named the Unimproved, or the Egyptian Greenfleshed Melon Ruined. The true old Egyptian Greenfleshed, when well grown, is far better than this is in flavour, but not in size; but of what use is size without flavour? Pitt's improved might certainly be useful for decorating the dessert table, but it must not be tasted, or it will at once be condemned. About four years ago six plants of this hybrid Melon were given to me by a friend. I planted them in a three-light box, two plants under each light, where they grew rapidly, producing fruit almost at each joint; they set, swelled, and ripened a fair crop of fruit much larger than those of the old Egyptian Greenfleshed Melons. Some of them weighed as much as 4 and 5 lbs., although my frames were far too narrow for the rambling growth of the plant. I sent one into the house for dessert, which was used, and the remainder were sent as presents, as they ripened, to the different branches of the family. To my great disappointment, however, not one single fruit was approved of by any one who tasted them. My own opinion is, that this hybrid is tasteless; the flesh is neither green nor white. Some gardener may perhaps say that I did not give it a fair trial or good treatment; but such is not the case; for in the same season in which I grew this hybrid I grew 18 lights of a good Persian variety on the same Melon ground, and with the same treatment, the same soil, &c.: the latter produced a heavy crop of fruit, of a most excellent flavour, and highly approved of by all who tasted them. It could not, therefore, be in cultivation that this hybrid lost its flavour. Last season I was determined to give it another trial. I grew six plants in a three-light box, two plants under each light as before; and in this instance I had an opportunity of giving it another fair trial, as the frames (newly made) were 7 feet in breadth, 2½ feet in depth in the back, and 2 feet in depth in front. This I considered ample space for the rambling habits of the Melon. They grew with rapidity, bearing fruit much larger than before. I sent one to table, which was not approved of; others were sent as presents, as they ripened; but none of them gave satisfaction. All other true sorts which were grown on the same ground, and with the same treatment, gave great satisfaction; therefore I consider this quite sufficient to convince any person that this hybrid, as well as many others, is quite useless.—*Wm. M'Donald, King's Road, Chelsea.*—[This is but an unprofitable dispute. No doubt many hybrid Melons are worthless; but how can we say that they are all bad when, for anything we know to the contrary, half the best sorts in cultivation are cross-bred? No doubt bad crosses will produce bad Melons, and good crosses good ones. Would a cross between the sweet Melon of Ispahan and the Beechwood be worthless? We suspect that it would be very much the contrary.]

Colour of Leaves affected by Soil.—Most manures seem to deepen the green of the leaf. But there are some Picotees and Carnations that generally have a sickly hue, and however well and carefully they may be layered, they are apt to rot, very often not until the following year, when they are in bloom; they will then die suddenly. Piping seems the only sure way of propagating them. It is said that salt and nitrate of soda have the effect of hardening plants. Would it answer to apply them in this instance, and if so, in what manner? Humphreys's Compound is said to harden. Nitrate of soda must be applied in much smaller quantities than Humphreys's Compound, but how much may be safely given I do not know; perhaps a teaspoonful to a gallon of water.—*G.*

Potatoes.—I observe, with some surprise, your remarks on Mr. Grey's experiments on the planting of Potatoes in autumn. You appear to think it quite necessary that the sets should be covered so deep that they cannot be reached by the frost; this is a very unnecessary precaution. Provided Potatoes are in dry soil, and completely covered by it, they will not be injured by the most severe frost—that is, supposing they are allowed to remain in the soil until they are completely thawed again. Hundreds of Potatoes are left in the ground all the winter, many of them not more than an inch deep, and yet, when they are turned up in the spring, they are as sound as if they had been kept in a cellar. If you doubt this, it is easy to test its truth, by covering up Potatoes now in the soil of a dry garden, to the depth of an inch or two, taking care that the light is thoroughly excluded, and take them up in the spring, when the frosts are over, and you will see that what I have stated is correct. On reading the article again, I observe you suggest the probability of Potatoes bearing frost when covered. As you solicit information about Potatoes, I beg to say that I have saved sets from the Lemon Kidneys grown in my own garden for the last dozen years, and they neither curl nor rot, which I attribute to their being left on the ground exposed to the sun until they become quite green, which appears to give so much excitability to them as not only to prevent rotting, but also to make the crop earlier the succeeding year.—*T. G.* [Since our correspondent's *experience* tells him that Potatoes are not affected by frost, if in the dark, we can only express our satisfaction at finding it agree with our qualified *expectations*. We should be sorry, however, to risk a crop buried but an inch deep in any land that we know of.]

Collecting Leaves.—In the Calendar of Operations for last week "W. P. A." recommends leaves to be drawn into ridges in the back part of the shrubberies, and there to lay and rot, if they are not wanted for other purposes. This I look at as being a very disorderly plan. Where do we see the shrubberies so thick as to hide those leaves for the twelvemonth round from the eye of our employers? If my master were to pass by leaves behind his shrubberies without noticing them, I should begin to think that, in the course of another year, he would also pass them by in front of the shrubberies without notice. It is well known that leaves, when rotted in a proper place, and dug into the ground before planting shrubs, are of very great assistance to the shrubs; but to scatter them on the surface of the ground is of no use; the spring months would dry them to a powder, and they would, comparatively speaking, be driven like chaff before the wind. I regard the advice of putting them in a fresh state into holes intended for American plants, as more likely to mislead than to advance any inexperienced person. What would have been the result of plants put in in such a way, after a summer like the past? Water would have been of no use in a hole filled with leaves at the bottom. And, in the case of snow with strong wind coming soon after the plants were planted, I should expect to see their roots turned up to the weather, particularly if they were large plants. Until such time as "W. P. A." can prove the good resulting from such a practice, the advice can be of no use to any one, except to those who wish to try it as an experiment.—*M. D.* [We insert this letter at the express request of the writer; but in doing so, we must add, that we entirely disagree with some of his opinions.]

The Peregrine Falcon.—I have a living specimen of this noble bird of prey, which came into my possession about six days ago; he is quite docile; takes *food* from the fingers; and apparently might be trained to fly at other birds with very little trouble. He was taken on the 27th of *last* month, in the neighbourhood of Wormwood Scrubs, by a London bird-catcher. He is a male in two years' plumage; and I can only add, that all I have read concerning the habits of this noted bird is verified in this one, as far as I have had the means of judging.—*John Milton.*

Wilmot's Black Hamburgh Grape.—With reference to this Grape I am enabled, from my experience at Welbeck, to state that it is not, as Mr. Mearns suspects, identical with the Welbeck Black Tripoli. Judging from appearance I for a long time after it was exhibited at Chiswick considered it the Tripoli, but on tasting it I was soon convinced of my error. Wilmot's Black Hamburgh, in point of flavour, is inferior to the common Hamburgh, while the Welbeck Black Tripoli is infinitely superior to that variety. Wilmot's Black Hamburgh is a very desirable variety, and worthy of a place in every late Vinery in the country, as it keeps better than most varieties; but the Welbeck Black Tripoli has no equal among black Grapes that I am aware of. This variety is not known in the London trade.—*W. P. Ayres, Brooklands, Blackheath Park.*

Shanking of Grapes.—At p. 749, an "Amateur" complains that his Vines grew the first year with great vigour, and in the second year produced a considerable quantity of fruit, most of which shanked off. I am not surprised at this. I am confident that the late venerable President of the Horticultural Society would not have sanctioned the cropping of the Vines in the second year after planting, when he approved of the plan for the borders. Surely the considerable quantity of fruit which was left on those Vines to ripen, would demand more secreted matter for their maturation than the leaves were able to store up in the system of the plants, under the most favourable influences that possibly could be. An "Amateur" observes further, that in the previous summer many of the largest Vine-leaves damped off and fell, having rotted near the base of the footstalks. To this I should say, that the larger the leaf, the greater the surface exposed to light and heat; consequently, it would perspire more than a leaf of less size, and part

with a greater quantity of light than the roots could transmit to it, on account of the leaves being in a warmer medium than the roots. See Mr. Lindley's "Theory of Horticulture," pages 50 and 95. But the disease originates from more causes than one, viz.:—The principal cause is the roots of Vines being in a medium much colder than that of the leaves and branches, produced either by an excess of water in the soil occupied by the roots, which prevents its being heated by solar influence until this water is evaporated—the effect of which is to lower the amount of warmth in the soil; or from the border being shaded, by plants or otherwise. From the plants not being preserved in a sufficiently healthy state to decompose, or assimilate, the whole of the aqueous matter taken up by the roots, to mature their wood perfectly, and to be able to store up in the interior of the plants a sufficient amount of secreted matter to be able to meet the demand of the quantity of fruit left on them to ripen. Over excitement. By this is meant a too high night temperature; and also a high temperature in dull weather, when the leaves are unable to perform their functions in the absence of solar light, at the same time being exposed to a too high degree of fire-heat; and at no time does this treatment act more deleteriously than when Grapes are undergoing the ripening process. One of the first gardeners in England says, that notwithstanding the many conjectures and conflicting opinions respecting shanking, its undoubted cause is at the roots, originating from a cold or retentive soil, or from imperfect drainage, or from the Vines having been planted too deep. To one or other of the above faults, every case of shanking I have experienced was attributable. I have a large house having a thoroughly drained and shallow border, in which there is no shanking; while Vines planted in an old border, and having their roots deep, are shanked at the extremities of the branches. The whole of the Vines are exposed to the same temperature, and the same internal treatment.—*G. G. Watson, Vicarage, Norton.*

Gardeners' Benevolent Society.—I am afraid the remarks of Mr. Whiting, relative to this Society, are too true; and there is another item in the management which appears to be wrong, and one which I know is doing the Society considerable injury. I allude to the extravagant charge of *fifteen shillings* each for the Annual Dinner, a sum considerably higher than the majority of gardeners can afford for one night's entertainment. Last January I had engaged to meet several friends at the dinner, *five* of which would have joined the Society, but when the price of the Tickets was announced, they declined the invitation. I wrote to the Chairman (Mr. Noble), stating the fact, and giving my reasons for not attending, and solicited him to read the letter to the company, but he declined to do so. A few days afterwards I received a note from him stating that he did not conceive my letter related to the meeting, and that "he did not see how a dinner, with an unlimited quantity of wine, could be got up for less than 15s." An unlimited quantity of wine! What, in the name of conscience, do gardeners want with an unlimited quantity of wine? If wine-bibbers like to drink their half-dozen bottles, let them pay for it; but do not tax the man who would be satisfied with one pint, because his neighbour likes to drink ten pints. A member of the Committee told me if the dinner-tickets were lower, gentlemen would not attend, and therefore the Society would lose their donations. This may be all very true, but I do not believe it. Am I to suppose a gentleman disposed to contribute to the funds of the Society would absent himself from the dinner, merely because the price was not such as to exclude gardeners? No: that benevolent spirit which prompts them to contribute towards the support of the poor and indigent of our class would forbid that they should refuse to meet the hale and hearty for so noble a purpose. *If*, however, the Committee think otherwise, let them *provide two tables*, one for the patrons, and the other for the patronised; but, at any rate, let the "poor gardener" have a chance of dining without expending the whole of his week's earnings. I throw these hints out for the consideration of the Committee, believing that they are more likely to be influenced by a public notice than by any private recommendation.—*William P. Ayres, Brooklands.*

[Why have a dinner at all? It would be much wiser in those who can afford to throw away their money upon a bad tavern dinner to give this money to the charity. Nothing can possibly be more absurd than the English practice of persuading people to pay a guinea for a dinner, in order to obtain another guinea for the charity after dinner.]

Brewing.—I cannot agree with "Sandleford-stone," that good beer can be made without boiling the wort; it may answer for present use, but it is far from being wholesome or clear. In order to make good pale ale beer, take one barrel and a quarter of liquid (summer) bushels of malt; steep the Hops in boiling water for three hours, then throw it into the boiler with the whole of the wort, and boil gently for two hours (with the cover on, or it will waste and lose its strength); then take it off the fire, and put it into coolers; when cold enough add yeast; in 16 or 18 hours afterwards turn it into casks, and keep filling them up well for a few days. I often brewed the above quantity three times a week during summer, and occasionally omitted boiling it properly, and consequently I had it thick and poor.—*A Farmer's Daughter.*

Hints for Nurserymen.—I wish to call the attention of nurserymen to the following suggestion, because I think that some plan resembling that which I am now about to propose might, if adopted, be profitable alike to both buyer and seller. What I would recommend then is, that some of our nurserymen would now and then publish a short list of ornamental plants, with prices, subjoining an enticing little P.S. to this effect,—that all purchasers (say) to the amount of 21s., selecting their plants from the above list, and paying ready money for the same, should be entitled, as a bonus, to additional plants to the value of —— to be selected either from the same, or from a second list of plants, which might likely consist of such articles only as the owner had a superfluity of.—*Sorew.*

Chrysanthemums.—The cause of these flowering so late in the season is owing to their growth not being accelerated early enough. Let firm cuttings be put in, in October or November; this will cause the plants to develop flower-buds a month earlier in the succeeding autumn. Put cuttings singly into small pots, and keep them in these until March; then shift them into pots, larger and larger as they advance in growth. Place them in a moderate hotbed, and keep them growing in the frame until May; when about 1 foot high, stop them, which will cause every bud to push. Retain five or six shoots, and rub all the others off as they appear. Place them on a sunny border, about a foot apart every way, and never allow them to want water in the hot weather. Keep on shifting, using loam and dung, until they are in 24-sized pots. When they begin to show flower-buds, stimulate them by using guano or other liquid manure, which will make them produce flowers early. This is of great consequence, if they are wanted to bloom out of doors. To have them in perfection, when in flower, remove them to an airy greenhouse, as no plant suffers so much from confinement, where they speedily lose the leaves, and run up to naked, unsightly stems, destitute of foliage. By attending to these directions, fine dwarf-plants will be produced, clothed with rich dark-green leaves and large flowers.—*J. R.*

Chrysanthemums.—With respect to "C. P.'s" Chrysanthemums (p. 752). I think he will find that his border is too rich for such varieties. All the light kinds are obtained by getting rid of colour, to which the plants, when grown too luxuriantly, have a tendency to return.—*Corylus.*

Miscellaneous.—*Caledonia*, in reference to the paragraph by "J. R.," p. 765, observes that the Almond (Amygdalus communis) bears profusely, and ripens its fruit at the distance of 700 miles north from London. The Mulberry, too, he says, matures good crops of fine fruit at the same distance from the metropolis.

Societies.

HORTICULTURAL SOCIETY.

Dec. 3.—R. W. Barchard, Esq. in the Chair. At this Meeting, among Plants, perhaps the greatest novelty was a small specimen of a stove plant from Messrs. Henderson, of Pine-apple-place, named Hesemasandra aurantiaca, but appearing to be an Aphelandra of some sort, with most beautiful orange and yellow blossoms. It was said to have been received from the Continent about two years ago, from Mr. Makoy; this was probably the first time of its flowering in this country. If, as is probable, it can be grown to the same size, and brought to the same state of perfection to which A. cristata often is, it will prove an exceedingly valuable addition to our autumn-flowering stove plants. A large Silver Medal was awarded for it.—From Mr. Plant, gr. to J. H. Schroder, Esq., was a handsome plant of the old Phaius grandifolius, in fine bloom; also Zygopetalum rostratum, Brassia Wrayæ, and a good plant of Dendrobium Pierardii. A Banksian Medal was awarded for the two last-named plants.—Messrs Veitch and Son, of Exeter, sent two new sorts of Tropæolum; one, a yellow flowering variety, was not named; the other, a scarlet, was named Lobbianum, in honour of their collector, Mr. Lobb, who sent it from Peru; it had on it one fully-expanded bloom, of a very brilliant scarlet, and, judging from its numerous flower-buds, it has every appearance of being a free bloomer. A Banksian Medal was awarded for it.—From Mr. Gaines, of Battersea, was a plant of Cynoglossum cœlestinum, and two seedling Corræas, one with rose-coloured blossoms, the other with pale-green flowers.—From Mrs. Wray, of Oakfield, was a cut specimen of the scarce Epidendrum rhizophorum, a species resembling E. elongatum, and remarkable for its gay bright orange blossoms.—Mr. Stanley, gr. to H. Berens, Esq., sent a good specimen of the old Cymbidium sinense, which, being very fragrant, is exceedingly suitable for placing in sitting-rooms.—From Mr. Tant, gr. to E. Johnston, Esq., was a box containing 14 beautiful cut blooms of Chrysanthemums.—Mr. Hamp, gr. to J. Thorne, Esq., sent a cut specimen of Habrothamnus elegans, or purpureus, with pale violet blossoms.—Of Fruit, there were two Pine-apples from Mr. Sheeres, gr. at Bohun Lodge, East Barnet; one, an Enville, weighed 6 lbs., and measured 18½ inches in circumference, and 1 foot in length; the number of pips in height was 10. The other was a Queen, weighing 4 lbs. 1oz., and measuring 16 inches in circumference and 8½ inches in length; the number of pips in height was 9. These were both handsome fruit.—G. Crawshay, Esq., of Colney Hatch, showed fine bunches of Black Hamburgh Grapes in excellent condition, the berries being quite plump, with a firm juicy flesh. They had been grown, as has been formerly mentioned, without the aid of fire-heat, except about this time of the year, when slight fires are put on through the day, solely for the purpose of drying up damp, which it is well known would soon destroy ripe Grapes at this season. Air is, however, given both at back and front of the house while the fire is in operation, and when the house is shut up at night the fire is withdrawn. Mr. Crawshay stated that he has now 400 bunches in a variety of the ordinary size, in equally good condition with those exhibited.—From J. Moorman, Esq., was a collection of Pears, consisting of fine specimens of Marie Louise, in excellent condition; Beurré d'Aremberg; Yan Mons Leon Le Clerc, a Flemish variety of modern introduction; and Beurré Diel, the latter very fine.—Good specimens of Apples and Pears were also shown by Mr. Errington, gr. to Sir P. G. Egerton, Bart., M.P.—Mr. Cockburn, gr. to the Earl of Mansfield, Kenwood, sent fine large roots of Oxalis Deppei. This, although not equal to the Potato, is a very useful variety of vegetable, ranking with Jerusalem Artichokes, Scorzonera, and such like plants. Notwithstanding the unfavourable season we have had for tap-roots, such as this is, those exhibited were excellent specimens, and showed to what perfection the root may be brought when properly cultivated.—Among miscellaneous objects were two Slate Pots, from Mr. Beck, of Isleworth, who has in this instance improved these excellent contrivances, by putting a rim similar to that of the common garden-pot, round the top, by which they not only look neater, but may be lifted with much greater ease.—From the garden of the Society was a collection of Chrysanthemums which, although well-grown plants, were not in fine bloom, owing to their having been placed in the conservatory too early; and not having been sufficiently exposed to light there, the plants grew rapidly after they were introduced into the house, became drawn, and were consequently unable to fully expand their flowers. Four of the plants exhibited, had been watered with Potter's concentrated liquid guano, which was given to them at three different times, viz. on the 1st of August, on the 27th of the same month, and on the 10th of September: it was applied to them in the water with which they were watered, at the rate of 4 table-spoonfuls to 3 gallons of water. Other four plants in the same group were watered with guano-water at the period above mentioned; the liquid was mixed at the rate of 2 oz. of guano to 3 gallons of water; and, finally, seven other plants received manure-water once a week, from the 1st of August until the middle of October. In other respects, the whole received exactly the same treatment as regards soil, &c.; they all grew very much alike; indeed, so little difference existed among the plants in general, that it was almost impossible to have said which was the best among them.—Of fruit from the gardens there were, among Apples, Tower of Glammis—a sound keeping, excellent kitchen Apple; Padley's Pippin, resembling the Golden Harvey, very hardy and exceedingly useful for all purposes of the table; Beachamwell; Dutch Mignonne; Reinette du Canada; and Pomme Royale: the latter being a sort of Russet, is a good keeper.—Among Pears were Broom Park, a hardy variety, raised by Mr. Knight, which has proved to be good when grown as a standard; Passe Colmar; Glout Morceau; Beurré d'Aremberg; Knight's Monarch, which maintains its good character; and Winter Nelis, a variety which should have a place in every collection, on account of its excellence. Many Pears, generally good, are not always so in all seasons, but this variety is invariably excellent. Fluctuations of the season do not affect its quality, which is a consideration worth attention by Pear-growers.

LINNEAN SOCIETY.

Dec. 3.—Edward Forster, Esq., in the Chair. A species of Triton caught at Putney was exhibited.—Mr. Hogg presented to the museum a new form of a Chenopodiaceous plant.—A Paper was read from Mr. Main, A.L.S., on Vegetable Physiology, in which the author endeavoured to state his own views in opposition to those generally received by vegetable physiologists. He maintained that there was no proof of the ordinarily received notion of the descent of the sap; that the tissues were nourished by, but not formed or developed out of the elements of the sap; that the tissues of the tree were infinitely extensible, and formed by a vital process out of the cambium, which he called the indusium or vital membrane, and which was the only true source of all vegetable tissue. The cambium is not formed by the leaves, or any other agent, but by itself. The true function of the leaves is to draw up the sap into the tree, which they effect by the transpiration of the fluid part of the sap through their tissues.

ENTOMOLOGICAL SOCIETY.

Dec. 2.—Geo. Newport, Esq., President, in the chair.—Mr. Des Vignes exhibited a specimen of the Coccinella lineata, of Fabricius, now known as a variety of C. ocellata, which was taken in Great Britain.—Mr. Pelerin exhibited the larvæ, supposed to be of a species of Hepialus, from New Zealand, from which protruded a fungus 5 or 6 inches in length.—Mr. Bond also exhibited a specimen of the larva of the Drinker Moth, which was covered with a plant of fungoid character, and closely resembling the Muscardine, which attacks the Silk-worm.—Mr. Weaver exhibited the cases of the Forrectaria ubiciplacella, which were of a horny consistence, and in form resembled the shell of a dentalium.—Mr. Westerman exhibited a new species of Carabus, from Guinea.—Mr. Westwood also exhibited drawings of two new species of the same genus.—Mr. Evans exhibited a collection of insects from New Holland, consisting principally of Hymenoptera and Neuroptera.—Mr. Milton brought down to the Society some larvæ, which he had taken from the nest of a pheasant, and which belonged to a species of Tipula. The larvæ were alive when the bird was opened; and, on being counted, numbered 252. Mr. Spence pointed out the importance of this fact, as the larvæ of the species of Tipula were very destructive

to the roots of various plants.—Mr. Saunders exhibited a Dragon-fly, which had been caught at sea, at the mouth of Africa, 600 miles from land. The question of the possibility of the insect flying so far from land was raised by the President, Messrs. Bennett, Saunders, Farrell, and the conclusion arrived at was, that this insect had driven from the shore by the winds.—Mr. Saunders stated he had also seen Dragon-flies at sea, above 100 miles from land.—Mr. Waterhouse exhibited two rare insects from the collection of the British Museum; the one a Grasshopper (Mastigocera? gazifer), from Sumatra, remarkable for the length of its proboscis; the other a species of Mutilla, belonging to the genus Corynis, remarkable for its grey plumage and the form of its wings, and forming a link between the two great families of Lepidoptera.—Drawings were exhibited from Captain Boys, of India, of a species of Cimex, with its larva, which was covered with spines. It was found on the leaves of the Cocoanut gratissimum. A species of Coleoptera, approaching the form of Ips, was exhibited also from Captain Boys.—A paper was read from W. Stephenson, Esq., Surgeon, on the Entomology of New Zealand. The Coleoptera are exceedingly abundant, and their larvæ assist much in the destruction of the hard wood of the numerous forest trees. No Buprestidæ had been observed. The larva of a Hepialus was found exceedingly destructive in gardens. An account was given of a formidable insect, allied to Gryllus, which lived chiefly in decayed trees, and was carnivorous, and which inflicted severe wounds upon those who interfered with it.

COUNTRY SHOWS.

Norfolk and Norwich Horticultural Society, Nov. 27.—This was the annual Show, which was better attended than we remember to have seen it upon any former occasion. The Chrysanthemums were very creditable, and presented many beautiful varieties, including Grand Napoleon, Vesta, Empress, Defiance, Unique, Queen, and several others. Mr. Bell exhibited the following:—*Chrysanthemums, 32 varieties:* Maréchal de Crequi, sanguineum, Ibotata, Malvina, mirabile, Bijou, insigne, Louis-Philippe, Marie Antoinette, Conquerur, Madame Pompadour, Theresa, Luxurie, Hero, Unique, Vesta, sulphurea, Incurved Pink, Mamado, Casimir Perrier, Ivanhoe, Empress, Adventurer, Defiance, Grand Napoleon, Phillis, Colonel Combes, perspicuum, Marchioness de Montebello, Achmet Bey, Surprise, and Phidias. *Ericas:* Linnæoides, hyemalis, cafra, arbuscula, and pyramidalis. *Miscellaneous Plants:* Epacris grandiflora, Ardisia crenulata, Geneira longiflora, Leschenaultia formosa, Cactus truncatus, Cypripedium insigne, and Ipomopsis picta. MEMBERS' FLOWERS—*Chrysanthemums, best* 24: Rev. J. Burroughes—Marshal Maison, Beauty, Vesta, Golden Lotus, pulcherrimum, Empress, Defiance, Tasselled Yellow, Princess Marie, Chancellor, formosum, Marie, Duke, Cluster Yellow, Minerva, Malvina, sulphureum, Luxurie, perspicuum, Tasselled Lilac, lucidum, elegans, and Starry Purple. *Best* 18: Mr. Short, gr. to H. N. Burroughes, Esq.—Luxurie, Campestroni, Chancellor, Peter, Duke, Minerva, Achmet Bey, Beauty, formosum, Duc de Calineau, Memnon, Tasselled Yellow, Louis-Philippe, Marshal Maison, Two-coloured Incurved, Defiance, Hero, and Cluster Yellow. *Best* 12: Rev. J. Burroughes—Duchess de Montebello, Vesta, Duke, Tasselled Yellow, pulcherrimum, Cluster Yellow, Defiance, Fischier, Golden Lotus, Marie, formosum, and Sultana. *Primula sinensis, best collection*: Mr. Spence, gr. to Sir W. B. Proctor, Bart. *Ureschera zebrina, collection of*: Mr. Emms. *Lemon tree, &c., to fruit*: Mr. Emms. *Combretum purpureum*: Colonel Petre. FRUITS.—*Grapes*: 1, Muscat, W. Gale, gr. to H. N. Burroughes, Esq., M.P.; 2, Hamburgh, Mr. Rippingale, gr. to G. Morse, Esq.; 3, Muscat, Rev. G. Lucas. *Extra*, Hamburgh, Mr. Aldborough, gr. to Mrs. Kett. *Grapes, out door*: 1, Muscadine, Mr. Spence; 2, Mr. Colman. *Plums*: Imperatrice, Mr. Short, gr. to J. Stracey, Esq. *White Currants*: Mr. Short. *Red Currants*: Mr. Short. *Cranberries*: Mr. Short. *Apples*: Golden Harvey, Mr. Short. *Pears, dessert*: 1, Marie Louise, Mr. J. Cann; 2, Crassane, Mr. Warner, gr. to W. Robinson, Esq.; 3, Black Worcester, Mr. J. Wighton, gr. to Lord Stafford. *Medlars*: Nottingham, Mr. Gale. *Pears, baking*: 1, Uvedale St. Germain, Rev. G. Lucas; 2, Catillac, Mr. Short. *Walnuts, this shelled*: Mr. Scarlett. VEGETABLES.—*Celery*: 1, Crawshay's Solid Red, C. K. Tompson, Esq.; 2, White, Mr. Short. *Carrots*: Altringham, Mr. Gale. *Parsnips*. Hollow Crown, Mr. Gale. *Lettuces*: 1, Brown Cos, Mr. Jacobs, gr. to Mrs. Scott; 2, Texter Cabbage, J. Elwon, Esq. *Peas*: Shilling's Early Grotto, Rev. J. Burroughes. *Potatoes*: Cambridge Kidney, H. S. Patteson, Esq. *Red Cabbage*: Colonel Petre. *Sea-kale*: Mr. Short. *Horse Radish*: Mr. J. Potter. *Broccoli*: White Cape, Mr. Short.—*Norwich Mercury.*

Reviews.

Sowerby's Supplement to English Botany. Second Series.

We wish to call the attention of the readers of the *Gardeners' Chronicle* to this very beautiful work, which is now publishing at intervals of two months, as it seems highly probable that many of them, who take an interest in botanical pursuits,—and what possessor of a garden ought not to do so?—are ignorant of its existence. Of the present series six Numbers have now been published, each containing *four* plates of new or recently discovered native plants, executed in the very highest style of art, and also most accurate in the delineation of the several parts requisite for scientific study. Each plate is accompanied by one, two, or more pages of letter-press, giving the generic and specific characters, synonyms, and a detailed description of the plant; together with, when requisite, observations on its peculiarities, and critical remarks concerning it. The literary part of the work is in all cases prepared by some botanist of note who has turned his attention to that part of the subject to which the respective plants belong, and his initials are appended to each article.

From the large number of copies of the original English Botany, which have been sold, it is manifest that very many persons must possess that work who have not as yet rendered it complete by obtaining the Supplement; for if such had not been the case it would now have to be stated that the sale of that Supplement is so small (considerably under 500 copies) as not to pay its expenses, even when (as in this case) the artist, engraver, colourer, publisher, and proprietor, are the same person. We trust that the study of botany will [illegible] work which does so much credit to the country to fall to the ground for want of support, and would also recommend it to the ladies as an elegant appendage to the greenhouse and drawing-room. It should be remembered that no country possesses a collection of figures of its native plants, making even nearly the same approach to perfection as is done for Britain by the English Botany and its Supplement. The Supplement was advertised in the early Numbers of this Journal for 1844.—*C. C, B.*

A History of British Crustacea. By Thomas Bell, F.R.S., &c. Part I. Van Voorst.

THIS is the first part of another work of the series on British Zoology, published by Mr. Van Voorst. We had feared that the interest in natural history was too little to allow of the publication of any works in this series upon the invertebrate animals of Great Britain. We are, however, glad to find that Mr. Van Voorst is disposed to extend his design to the whole animal kingdom. The present work embraces the Crustacea, by Professor Bell, whose knowledge of this subject is well known to naturalists, and will be a guarantee for the successful issue of the work. The description of each species is accompanied with a wood engraving, and an account is given of its habits, uses, and other interesting information. In the present Part also, there are several vignettes, the subjects of which are selected with much good taste. We hope these works will meet with such encouragement as will induce the publisher to give the remainder of the British Fauna in the same manner, as we believe one great reason why zoology is not pursued with equal interest to its sister science, botany, is the want of works giving accurate descriptions of our native animals. In the point of "getting up" the work promises to be worthy the series of which it forms a part.

The Naturalists' Pocket Almanac (Van Voorst), is a poor affair, and unworthy its publisher. The idea of it is good; the execution bad. The plan of the book is to combine with a common Almanac monthly notices, Zoological and Botanical, to which the observer may add memoranda of his own upon interleaved paper. If these notes were copious and well selected, they would be interesting and useful; but their value depends essentially upon their copiousness. A few petty details are productive of no advantage to the reader. In the trifle before us they are meagre in the extreme. For example, the writer has not a word to say about the plants that flower in March, April, and June—the three months of the year most interesting to the accurate observer; and in May the most important fact that he announces is that the Lily of the Valley is in flower. Near the end is a meagre list of the periods at which a few common plants have been observed to flower for *four* years; but the list is far too short, and not all contrasted with the remarks of other observers elsewhere. In short, the Almanac seems intended for the special information of those who live in Epping Forest or its neighbourhood. The Entomological information is more copious and useful, as far as it goes; but it has the great fault of admitting a nomenclature so unusual in this country, that our best Entomologists are sometimes puzzled to know what the insects are to which the names belong. Almanacs are for popular purposes, and, to have any sort of utility, must be written in common language. Neither can we compliment the author upon his accuracy. There is no such Secretary of the Horticultural Society as Dr. Anderson; there is no such English plant as Whitehorn.

Miscellaneous.

Shanghae Trefoil (Medicago denticulata).—A fine broad-leaved variety of this plant was found by Mr. Fortune to be much used by the Chinese in the winter months as a vegetable. Afterwards they manure the rice-grounds with it—indeed it is often sown expressly for that purpose. It is, however, hardly to be expected that it should answer that purpose in England. We understand that the Horticultural Society have received a few seeds of the variety.

Defence of Speculation.—One would think that in thinking there were something wicked or else unwise; everybody feels or fancies a necessity of disclaiming it. "I am not given to speculation"—"I am no friend to theories." Speculation—theory—what is it but thinking? Can a man disclaim speculation—can he disclaim theory, without disclaiming thought? If they do not mean thought, they mean nothing; for unless it be a little more thought than ordinary, theory, speculation, mean nothing.—*Benthamiana.*

New Zealand.—We have just heard of a valuable case of plants received by a gentleman in this settlement, by the Theresa, which were packed in wet Moss without any soil at the roots, and soldered in tin. This mode of packing answers remarkably well, as every tree appears to be alive and healthy. Fruit trees may be thus obtained from England at considerably less cost than we have been accustomed to pay for them from the surrounding Colonies, besides the advantage of inquiring the best descriptions.—*Nelson Examiner, April* 27, 1844.——A Meeting of the Agricultural and Horticultural Society was held, C. E. Drewe, Esq., the Provincial Judge, in the Chair. It was moved by Mr. F. D. Bell, seconded by Mr. J. S. Tytler—That the cordial thanks of the Society be presented to James Robert Gowen, Esq., for the interest he has manifested in its proceedings, and for his kind exertions in procuring donations of plants and seeds for this settlement. The following gentlemen were elected officers for the ensuing year:—Patron, J. R. Gowen, Esq. At Nelson; President, W. Fox, Esq.; Vice-President, G. Duppa, Esq.; Treasurer, A. MacDonald, Esq.; Committee, Messrs. J. S. Tytler, Kerr, Redwood, Dillon, Elliott, Cautley, Domett, Mackhanie, A. Saunders, Brewer, Bell; Secretary, Mr. Cautley.——*July* 4.——I have paid every attention in my power to your recommendations. Trotter, the gardener, has ample employment in private gardens; he told me to-day, that he had seven days' work to perform in six working days in the week. My garden has progressed very much lately. We had nearly 100 fine ripe Peaches, and are now eating some tolerable Grapes. I believe I have four hives of Bees, but some have been deserted. I think the bees an excellent occasion for laying up a store for the winter, as there are flowers all the winter; but they swarm too often, sometimes four or five times in a season.—*Col. Wakefield.* (*Private Letter, July* 5, 1844.)

Botanic Garden, Calcutta.—Dr. Wallich has been directed to carry out all the changes in this establishment advocated by Mr. Griffith, who has quitted his charge of the garden and returned to Malacca; but I regret to say, that little has been done since Dr. W.'s return. Indeed, the last time I was in the garden all the new ground arranged by Mr. Griffith was overrun with weeds! The Agricultural Society of Calcutta has determined to attempt the introduction of all the valuable fruits of all tropical countries, for dispersion in India, and Sir L. Peel gives a prize gratuitously for fruit and flower exhibitions.

The Black Indigo.—We learn, by a letter from Mr. Griffith, that this substance, mentioned at p. 879, 1843, is procured from some species of Diospyrus, a plant of the order of Ebonies, and known for the blackness and hardness of the wood, and acerbity and astringency of the immature fruit. Mr. A. Robertson is said to be engaged on an analysis of the fruit, and in the meantime agrees that, in consequence of the general character for astringency of the family, it is probable that the black dye is not in itself a black dye. This is likewise suggested by the published analysis of the dye stuffs, in which iron was found. This species of Diospyrus Mr. Griffith suspects to be unpublished.

Florists' Flowers.—We understand that the North Country growers intend holding several Exhibitions at Mr. Wood's, of the Coppice, near Nottingham, during the coming summer, which are to be open to the growers of the United Kingdom, and of which advertisements will appear early in January next. The first will be of Tulips and Pansies; the former of which will be exhibited in stands of 6s or 12s; and the latter in stands of 12s or 24s. There will also be prizes for the best pans of Breeder Tulips. The second Show will consist of Carnations and Picotees, and from the impetus given to the cultivation of these beautiful flowers (by the Exhibition of last season), in the immediate neighbourhood of Nottingham, a spirited competition is expected.

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

THE highest night temperature in the stove for this month should not exceed 60°, which may be maintained as long as the weather keeps open; should the weather, however, suddenly change to hard frost, do not strive to keep up this temperature by strong fires; 50° is high enough in very severe weather, and strong fires will be needed even to keep up that heat, so that in many cases water must be sprinkled over the paths, pipes, &c., to prevent the highly-dried air from injuring the plants. Strong stove climbers that do not blossom freely should now be root-pruned by cutting off some of their largest roots near the surface, or if they are to be taken up next spring and tried in boxes, this is a good time to begin to prepare them, not however, by cutting their roots, but by tracing one half of them to their extremities, and then placing them near the surface with some light compost thrown in amongst them; by the end of January these roots will have formed a fresh set of young fibres, and then the other half of the roots may be served after the same manner, but leaving the plant in the same place till later in the spring; this is a safe mode of treating plants that are to be removed from the borders of any of the houses, or for checking their luxuriance.

Conservatory.—Euphorbia jacquiniflora is an excellent conservatory plant while it is in blossom, but at other times it must have the stove treatment. Last season, about this time, I pruned some large plants of it, to see if by a little forcing in spring I could get them to flower early this winter, but the experiment failed in some measure; as soon as these plants began growing in spring, they also flowered on the young growth, but not satisfactorily, and now they are not more forward than others that flowered last Christmas, and that were pruned in January; these are now just beginning to flower, and by the middle of the month will be fully out. In another season or two this treatment, with the same plants, will bring them into blossom by the first week in December, and thus one of the best winter-flowering plants we possess may be had for the rooms or the conservatory for four months. The older the plants are, if they are kept in health, the earlier they can be brought into blossom, as they do not grow so freely; to get plants in this state, pieces of the oldest roots should be made into cuttings at potting-time, as Mr. Threlkeld has shown in a former Number.

Greenhouse, Pits, &c.—Such a season as this proves how useful temporary structures are for protecting greenhouse plants late in the autumn; the general plan is to cram all the pits and houses on the first appearance of frost in October, whereas almost all the plants of this division might yet be partially in the open air, and be much benefited by the treatment. For some families of plants—Pelargoniums, for instance—that are worked much out of season, contrivances of this sort are particularly useful. To have fine specimens of Pelargoniums in blossom in August and September, October is the best time to cut down the plants, and from that time till after Christmas they should be as much exposed in the open air as rain and frost will permit them; they will only be coming into leaf again, and after two months' protection in the greenhouse, &c. they may again be turned out into temporary pits to keep them back, and as the warm weather comes they may be placed under a north wall, &c.—*D. B.*

II.—FLORISTS' FLOWERS.

The Florist may now take breath. His Tulips are all safely in the ground and in a growing state, and comparatively speaking out of harm's way. He may now occasionally "overhaul" his collection by looking through his beds, when his favourite flowers will engage him with all their beauties to his fervent (poetical), we need not enlarge on his feelings, for those only who

have experienced them can appreciate how pleasurable they are The Carnation-grower's great care must now be to prepare his compost for next season (for most assuredly it will be a busy one) His turf must be turned often, very often, during the next three months, carefully picking out of it the Florist's plagues "the wire worm." The turf soil also must be shaken up and sweetened, and a proper quantity of thoroughly decomposed stable manure must be made sure of, let whatever other crop will, go without If he means to have large and fine flowers, he must not be too fastidious about manure, but it must be well rotten. Picotees are not so apt to become fat or as we call it, "ran," as Carnations, and they will, consequently bear a richer compost. Still, where Carnations and Picotees are grown for exhibition, one hundred pots might easily be cultivated at "high pressure," in order to win some of the prizes, which will be "thick as Blitherries" in the country next season, for those deservedly popular flowers *Pinks*—We have heard of many new sorts of these scented favourites both from north and south. We are told that Simmonds's Coronation, dark lace, and Burgess' Miss Jessop, black and white, are splendid flowers; the former having won several Cups in succession at Sheffield, till Bradshaw's Greenside carried off the palm this season Still we know that the Sheffield judgment and that of London are as yet as wide apart as the Antipodes Queen of Roses is not now to be obtained for "love or money" Headly's Duke of Northumberland is a 'clipper," and we are persuaded will become a general favourite, and the florist who has not yet got it had better make inquiry These, as well as Carnations and Picotees must be attended to now regularly The attention they want is comparatively trifling, but that little must not be neglected For other florists' flowers consult the Calendars of the last four weeks—*T F W*

IV.—PINERIES, VINERIES, &c.

Pineries—The weather of the last fortnight, having been dry, has been much in favour of Pines grown in pits heated by dung linings—not protected Have plenty of leaves and litter always in readiness to renew these linings, as one heavy shower will destroy the heat in those which have been long unturned The best plan is to make a rule of turning a portion of the linings every week On fine days dew the plants in the fruiting and succession pits heated by fire, with the syringe The atmosphere of dung pits will probably be sufficiently moist from the steam of the dung

Vineries—If the Vines started three weeks back are beginning to swell their buds be more careful to keep the temperature uniform—about 55 by night and 60 by day, must be maintained, allowing the house to rise to 70 with sun heat Long shoots should be bent down, so as to place the lowest buds uppermost, to cause them to break first, after which the rod may be gradually restored to its proper position You cannot keep too moist an atmosphere from this time till the Vines are in blossom Keep the soil of the outside borders at a temperature of about 70°, by covering it with leaves and litter as far as the roots extend Examine the inside borders occasionally and if dry, let them have a good soaking with liquid manure

Peach houses—Whenever you perceive the buds to be advancing, pay the strictest attention to the state of the atmosphere Give air when the sun raises the thermometer to 60°, and sprinkle the trees three times a day till nearly in bloom

Plants in Pits, now in bloom, should be assisted in setting by means of a camel hair brush Keep a temperature of 55 by night, and 65° by day If they are plunged, the bottom heat should not exceed 70°.

Strawberries—If Strawberries are required early a few may now be brought into a cool Vinery or a pit, the decayed leaves being first trimmed off, and a little of the top soil removed, and replaced with some fresh rich loam Wherever they are placed they should have gentle treatment at first, and all should be admitted freely every fine day—*G J*

V.—HARDY FRUIT AND KITCHEN GARDEN

Root pruning of Fruit trees now, in connection with Top pruning in Summer—In cases where several branches of a tree have become so luxuriant as to prevent a fair distribution of sap, or where altogether the growth has been so rampant as to prevent the formation of blossom buds, the cutting of the stronger roots, so as to check the too luxuriant branches, or the general pruning of the roots in cases of too vigorous though uniform growth, will be attended with advantage, inasmuch as vigorous growth and productive fruitfulness are severally effected by means directly the opposite of each other Though root pruning is now frequently referred to as something new it must be 15 or 16 years ago since I saw it resorted to by the late Mr Beattie, at Keene gardens, and I did not seem to think then that there was anything in it remarkable for novelty The practice frequently recommended, of cutting the roots every year or so, and then surrounding them with a trench of rich manure—though, I doubt not, attended with good results—possesses this anomalous feature, that the system owns the whole of its success to a perpetual doing and undoing; producing fertility by rendering the tree deficient in nourishment at one time, and supplying it with too much at another When trees are deficient in fertility from over luxuriance, the taking of the roots nearer the surface, giving no manure, but as mulching and attending to early and judicious summer pruning, we should prefer to a yearly mutilation of the roots unless in circumstances where it was desirable to have as many fruit bearing trees upon as small a space of land as possible Where the roots of Apples, Pears, &c are within from 9 to 18 inches of the surface, the trees may soon be deprived of extra luxuriance by judicious summer pruning, merely preserving as many leaves on the shoots as will insure a healthy action between the roots and the branches, and as few as will shade those buds at the base of the shoots and on small short spurs, that can only be reinforced fruitful by a free exposure to light and air In extreme cases, such as an old fine looking Pear-tree, that have become barren in the centre for want of feeding of the roots, and the supplying the tree with young wood, as previously recommended in the Calendar or as usually advised by Mr. Errington, would double it be attended with good results; but with trees of moderate age and equality of growth it will seldom be necessary unless in the case of trees of peculiar habit. Did I want anything to convince me of the utility of judicious shortening and thinning out the shoots (of Pear trees for example) in summer, it would be the sight of the fertile, healthy appearance of the Pear trees on the walls at the Horticultural Gardens, where, without having recourse either to root-pruning, or an annual laying in of young wood, the branches are studded all over with fruit buds close up to the stem

Celery—The present dry weather should be embraced for giving this useful vegetable its final earthing up. As we grow our crops chiefly in beds, and as our soil is apt to rust the Celery, I do not put on a great thickness of earth, but I think the beds up with tree leaves and any loose litter, putting them together when dry, and as lightly as possible, to keep them from forcing. The surface soon gets raked over, so as to entrude the most of the rain, and the frost is kept out and the Celery blanched by the same operation.—*R F*.

VI.—ARBORICULTURE.

Old Woods—As the weather still continues favourable for all operations of the season, every opportunity should be embraced for forwarding them.

Coppice—Now that the leaves have fallen, attend to the clearing of ditches, drains, and water courses; remove hedges, and plash the hedges where it is necessary, and forward all other work whenever the weather is favourable.

Young Plantations.—The planting of new ones, and carrying good fallowes in recently planted ones, should be prosecuted with as expeditiously as possible, when the weather is mild and the ground dry. It is best to keep the different sorts of oreat trees in masses or groups by themselves as much as possible, but this must be regulated according to the soil, situation &c Plant the kinds intended for permanent wood by themselves, intermixed with other suitable kinds as nurses, to be headed off, and kept low as undergrowth.

Nursery Work—The work to be done in this department, pointed out in previous Calendars, may still be proceeded with whenever the weather is favourable.—*W B*.

VII.—COTTAGERS' GARDENS.

This being about the best time for procuring a few Roses for the cottage garden, I would recommend those who are desirous of collecting a small group of good sorts to get the following which are mostly Perpetuals, or which flower from June until late in autumn, when frost puts an end to their beauty; viz., Bourbon, Acidalie, Bouquet de Flore, Duchess of Sutherland, P; Madame Laffay, P, Aubernon, Fulgare, P., Duc d'Athenle, Damask, Bernard, Crimson perpetual, Prince Charles, Boisgère, Goubault, Miss Sauvage, Comte de Paris, Triomphe de Luxembourg, Sylvain, Lady Fordwich, P; Lamarque, P, and Jeanne Desprez, P The above are all good, and are not expensive to buy Those marked P are well adapted for covering walls, or for training up pillars, &c. If planted in a bed they had better be placed in the centre, or wherever it is wished that the bed should be highest. China, Tea, and Noisette Roses, should be kept in pots until spring Other kinds may be planted with advantage about this season, when the weather is dry and not frosty The pruning of the Vine and other fruit-trees may now be proceeded with In pruning the Vine, cut out a portion of the old wood, especially where such can be replaced by well ripened shoots of last season All the young shoots should be more or less shortened according to their strength and maturity It is of no use to leave soft, unripe, or weak wood If left so thick as that the whole of the wall would be covered with foliage, the rays of the sun would be thereby prevented from heating the wall, and thus the latter would afford little assistance in ripening the crop It is, therefore, advisable to train thinly for by so doing the bunches will be larger and better ripened than could be obtained from crowded wood.—*J McH*

State of the Weather near London for the week ending Dec 5, 1844, as observed at the Horticultural Garden, Chiswick

Notices to Correspondents.

AMERICAN BLIGHT—*M C L*—Your tree is devoured by this insect Wash it all over in the spring, as soon as the blight appears, with spirits of tar, applied with a stiff brush After a few weeks more will appear; repeat the application A little perseverance will soon rid you of this pest, which in the long run would kill your trees

APPLES—*Malum*—The following table and dessert Apples will probably be found suitable for walls in Cornwall, at a considerable elevation above the level of the sea, viz Court Pendu Plat, Dutch Mignonne, Herefordshire Pearmain, Adams's Pearmain, Reinette du Canada, Ribston Pippin, Summer Pippin, Dumelow's Seedling Blenheim Pippin, Bedfordshire Foundling, Mère de Menage The Early Harvest may be planted a an early sort against a north wall, but this situation is more proper for kitchen fruit ‖

BEES—*Aquarius*—We are endeavouring to organise an Apiarian department of our Paper, in which all matters relating to Bees shall be sufficiently treated of You shall have an answer to your inquiry next week

BOOKS—*Georgie*—"The Modern Gardener," by T. Price It may be purchased for 1s 6d——*T Austin*—We are not booksellers You must apply to the publishers

CARNATIONS—*Rose in Usbe*—Potter a liquid guano has been tried on Carnations in the spring, when in a growing state with great success After the layers have become established in their blowing pots is the proper time to apply it; we should decidedly object to manure in *any shape* being mixed with the soil in which the layers are wintered ‖—*B*

CHICORY—*D T*—When used in coffee it is not deleterious, quite the contrary; it certainly imparts, when used in moderation a fine flavour.

CUCUMBER PITS—*C H*—We have given so many directions already for all sorts of structures of this kind, that we can find little to add By all means let your sashes be of wood If you have iron bars you will never be able to use them. Certainly use the flank system, and hot water gutters, not oil or pipes, for bottom-heating

DISEASE—*A*—The production on leaves of Hardenbergia consists of a mass of elongated cells perpendicular to the plane of the leaf It is accompanied by a very minute Acarus, to which probably it owes its origin There is also an obscure mould on the surface of the little patches If produced by the Acarus, which is most likely, it is very probable that it may extend to neighbouring plants, but if the little mould be the cause, this is not likely to be the case. *M. S. B.*

GOOSEBERRIES—*Carolus*—The varieties of Gooseberries can be obtained generally correct from the Lancashire growers. Amongst several hundred varieties which were obtained from various authorities by the Horticultural Society, there was great confusion as regards synonyms and false sorts them selves, as in any other class of fruits.‖

INSECTS—*Querist*—Our advice would not be so serviceable to you as a perusal of the article on the Wireworm, in the last Number of the Royal Agricultural Journal.—*A Subscriber*.—It is, no doubt, nearly related to the red spider and akin to the Aphides. The best remedies you will find enumerated with many curious histories in vol. i, p. 184, and following, of the Journal.——*A Beginner*.—The worms you sent must be from the decomposing parts of the plants, but it is still wood-lice [illegible] your seedling Auriculas.

LAUREL, LEAVES OF—*E. V*—We presume that dilute prussic acid would answer the same purpose as Laurel leaves in destroying the fruit spider; but there is a difficulty in knowing what the degree of solution should be, and an objection in the expense. Laurel leaves cost nothing, and are very easily applied. We shall be anxious to hear the result of your experiment Your explanation of the supposed fact, if it be a fact, is doubtless correct. We would, however, suggest that the soil of Spain is much warmer in winter than that of England.

MILDEW.—*C. W.*, and *Abrahamy*.—It is by no means uncommon for Chrysanthemums, &c., to be attacked with mildew at this season, The best way to prevent it is to syringe the plants well with nitre dissolved in water at the rate of 1 oz to a gallon This should be done as soon as the mildew makes its appearance. ‖

NAMES OF FRUITS—*S. R P. Shilton*.—1, Probably Minchal Crab, 5, Bedfordshire Foundling; 6, Hollandbury; 9, Lobb's Pearmain; 11, Hall Door; 12, Hughes's Golden Pippin; 16, Beurré Diel, 17, now past its season, but very probably the Gravenstein, 18, Cordwall is the Rymer, 19, Eve Apple (of some), not the Red Margaret; 20, Pike's Pearmain is King of the Pippins, 23, probably Keswick Codlin; 26, Dutch Mignonne; 27, Dumelow's Seedling; 28, 29, Beurré de Capiaumont; 33, Franklin's Golden Pippin, 34, Glout Morceau; 37, Bargelona Pearmain, 7, 30, 31, 32, correct Of the Seedlings, No 4 is the best, and seems worthy of further trial; 18 deserves further notice ‖—*W D F*—The Pear cultivated in your neighbourhood under the name of Forme de Marie Louise, is the Marie Louise, the other is the Black Aubas ‖——*B, D, Grays*—A fine specimen of the Bishop's Thumb ‖——*M L*—1, White Doyenné; 2, Brown Beurré; 3, decayed. 4, Stagg's Nonpareil, 6, Hollandbury, 8, Gloria Mundi, 7, Downton; 9, Beauty of Kent, 10, 11, Famagusta; 12, Golden Noble ‖—*Subscriber*

NAMES OF PLANTS—*C. M'I*—Epiphyllum violaceum. 2, Zygopetalum crinitum, 3, Maxillaria picta 3, M. punctata. 4, Bifrenaria racemosa, 5, Oncidium sanguineum, a small variety We do not recognise the shrub——*A Subscriber*.—Some kind of Eugenia, and a stove plant——*I*—The plant is *probably* Lælia flava; but we will not speak positively without seeing its flowers We never fix values on plants.——*Anon*—Polypodium vulgare, and some Commelina, perhaps Angustifolia——*H B*—Perna coccinea

NURSERY GROUND AUCTION DUTY.—*F V A*—The products of a nursery ground sold, as stated, are not, we think, liable to auction duty—*W*.

PEARS—*I. B*—1 or Perry the Barland, Holmore, Oldfield, Huffcap, and Taunton Squash, are amongst the most approved varieties ‖——*W*—If you can send a specimen of the Pear called in your neighbourhood the "Slippery," it will be attended to ‖

PEAR TREES—*W*—In planting, it would have been better if the holes which were filled with good soil had not been dug so deep as to penetrate the stiff clay The roots have been, in consequence, led into the very substance which has doubtless occasioned canker in the shoots The sorts, Swan's Egg, and Autumn Bergamot, are, however, more liable to canker, when old than many others All you can do is to supply the roots with fresh rich compost, and graft with Marie Louise, Knight's Monarch, or Althorp Crassane ‖

PELARGONIUMS—*An Anxious Inquirer* keeps her Pelargoniums too wet at this time of the year They should have water very seldom

PLANTING FOREST TREES—*R F*—In preparing ground on the side of a hill for planting where the soil is composed in many places of 8 inches in depth of good earth on a bed of chalk, and strong earth mixed with flints only trench the ground to the depth of the good soil, mixing a small quantity of the chalk or stronger earth from the bottom with it during the operation The best trees for such a bleak situation as the side of a high hill in Dorsetshire, are Evergreen Oaks, Weymouth and Cluster Pines, Silver and Spruce Firs, Scarlet and other Thorns, common and other Maples, Catalpa, Yew, Chichester Elm, and common and Manna Ash ¶

POTATOES—*I G*—What it is in soil that determines the quality of Potatoes is unascertained Opinion seems to turn in favour of saline manure, or guano, and against farm yard dung, unless very fresh and strawy Some lands never bring Potatoes of good quality

SOIL—*A South of the Soil*—The sap of trees rises from the soil till it reaches the leaves, then, under the influence of light, it is very much changed, a great deal of the watery part flies off; the remainder is converted into organisable matter, which is returned downwards, and lodged among the tissue, where it becomes wood, or is employed in the formation of new leaves and flowers, or is stored up in the form of starch, sugar, resin, and other secretions A small part is perhaps given off by the roots, under particular circumstances; but this is probably a deranged function

SULPHATE OF AMMONIA—*G*—The person who sold you this salt for nitrate of ammonia was either a cheat or a blockhead. It may be used with advantage for Potatoes But is it, after all, sulphate of ammonia? A dealer who blunders one way may blunder in another We never heard of its being applied to florists flowers, the danger will be in its making them too rank It would be a great convenience if you would be so obliging as write *on one side only* of your paper. We can find no such statement about guano on 26th Oct as you refer to.

THE SEA—*A J*—This may be propagated freely by suckers or by seeds, the latter should be gathered in October, when the fruit is dead ripe, mixed with sand, and turned over two or three times in the course of the winter, and, if sown in February, they will probably come up in May ‡

TRANSMUTATION OF CORN—We observe in a French Journal that Mr Thomas Biggs has shown in Cork specimens of Wheat from each side of which perfect Oats have grown These specimens are said to have grown on the estate of Shippool, belonging to Captain Herrick Could any of our Irish friends inform us whether this story is true, and if it is, procure us a sight of these ears of corn? We should be infinitely obliged, and would return them carefully. If they were addressed to Dr Lindley, 21, Regent street, unpaid, they would be promptly attended to.

MISCELLANEOUS—*E O L*—Your Carnation from Naples is the common Dianthus plumarius. We apprehend that in this case no change has taken place, but that your friend has been deceived by the Neapolitan who sold him his roots.——*Querist*—Early sorts of Potatoes are best adapted for late planting The Beurré de Capiaumont is in perfection in October. It is a great bearer, but has not so rich a flavour as many others of the same season Oaks are best grown from the Acorn, without having been transplanted ‡——*E M W*—The Cotoneaster microphylla may be grafted with success on the common Hawthorn If grafted, it should be done in the spring, but if budded, the operation should be performed after midsummer ¶——*R. J. H*—The Royal George and Noblesse are suitable Peaches for forcing in pots If the wood of your Vines is well ripened, it is not necessary to cover the branches with hay ropes after the Vines are turned out of the house ‡——*A Lady*.—Blanket is a vegetable.‡——*Abridged*.—The vols. for 1843 and 1844 are the third and fourth.——*R S, &c*.—The manure of applying nitrate of tar for the purpose of killing American blight on wall trees, is to embalm the trees from the wall, and with a pin make a hole, of any made of matting, to point over every part of the tree affected, taking care to rub the material well into all crannies and cracks.‡——*A New Reader*.—Oil paint is too expensive for you, calich, which may be bought for about 8d. a pail, done over with limed oil, is better than the old plan of whitening paper with the same material for the purpose of excluding light, as the latter is very liable to be torn. Calich, prepared with the composition above described, has been found to answer as well. With regard to Mexican Aloe Hedges, it is one of the most valuable extant.‡

*** As usual, many communications have been received to-day and others are unavoidably deferred for the present from the pressure of matter.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.—Dr. Lyon Playfair, C.B., Consulting Chemist to the Society, having kindly undertaken to deliver Two Lectures before the Members on the question of their country Journal Meeting, all Members will have the privilege of two additional tickets, to be obtained at the Office of the Society.

By Order of the Council,

12, Hanover-square, Dec. 4. JAMES HUDSON, Sec.

BURRIDGE AND HIS COOKING APPARATUS, combining Steaming, Roasting, Boiling, &c.—This Cooking Apparatus is believed to possess greater general advantages than any yet submitted to the public, both as regards strength of material and workmanship; in that, the laws of heat are so applied as to produce the greatest effect with the least consumption of fuel, without destruction to the apparatus; and B. and H. can safely recommend it, from experience, as unquestionably superior to anything of the kind hitherto made. A Prospectus can be forwarded, upon application, detailing particulars and prices, to 139, Fleet street.

The Agricultural Gazette.

SATURDAY, DECEMBER 7, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

WEDNESDAY, Dec. 11—Agricultural Society of England.
— — Smithfield Club Exhibition.
THURSDAY, Dec. 12—Agricultural Imp. Soc. of Ireland.
WEDNESDAY, Dec. 18—Agricultural Society of England.
THURSDAY, Dec. 19—Agricultural Imp. Soc. of Ireland.

FARMERS' CLUBS.

Dec. 10—Abergavenny.
Dec. 12—Richmondshire.
Grove Ferry.
Dec. 20—Wrentham.
Hicks Ferry.
Dec. 21—Rayleigh.
Dec. 21—Windsomb.

We have as yet received but few communications on the subject of our late remarks on FARMERS' CLUBS. We should feel exceedingly obliged if any of our readers living near the place of meeting of any such Society, would be kind enough to inquire of the Secretary if he has noticed our request, that information might be forwarded to our office of its name and place—of the days of its meetings for the ensuing year—of the subjects to be discussed on those days, if they have been determined on—of the subjects discussed during the past year, and of the resolutions arrived at on those subjects.

Of course, if any Society has determined on refusing the publication of these matters, we can have nothing further to say; only we are anxious that our request should at least be brought under the notice of all, and it can then be dealt with as may be thought proper. We believe, with many, that an attempt to centralise and connect or compare the now disjointed *dicta* of Farmers' Clubs would be beneficial. See page 769.

AMONG the many questions of interest which have been partially discussed at the agricultural meetings of the present year, is THE POLICY OF BREAKING UP INFERIOR PASTURE-LANDS.

The chief argument urged by the advocates of the proposal is, that such a change would give much additional employment at a time when it is much needed. With such a claim upon our notice, the question is certainly entitled to the fullest investigation. We are the more anxious, however, to enter into the merits of the case, because, up to the present period, the tenant farmer has universally been jealously restricted from adopting the system in *any* degree, or under any circumstances. Now, we are no friends to restrictions upon the good farmer, who is "up to the age," and who, endeavouring to get as much as he can from the soil, *gives* to it in the same proportion that he *takes* from it; at the same time, however, it must be conceded, that with the tenant-at-will they are, in some degree, *necessary* evils. The restriction alluded to, therefore, though in many cases it may be essential, in others is decidedly injurious; for, whether or not arable land be superior to pasture in creating profit and labour, there are unquestionably cases—many, too—in which lands that will not produce a *natural* crop, should be made to produce an *artificial* one.

The restriction we allude to is so universal, that the tenant farmer in but few cases ventures to question its propriety; and, indeed—so soon doth use breed habit, and habit mould the mind—many of our landowners also are convinced that it is *essential* to their interests, and ought, in all cases, to be preserved inviolate. No matter what the soil may be, whether it grows bad Grass or good, the tenant who should venture to suggest that he could pay his rent better, if allowed to cultivate and improve the whole of his naturally poor soils, instead of allowing one portion to remain in its originally unproductive condition, would often be looked upon with an eye of suspicion, and sometimes even be considered an agricultural pirate, whose design was to plunder the soil at the expense of its owner. A restriction like this, then, so general as to be applied to every description of soil, and under every sort of circumstance—a rule which ought to have so many exceptions, but which has been generally carried out with so few—cannot but have operated against the interests of agriculture. We therefore hail with pleasure the movement which has called for investigation into the principle upon which this restriction is founded; for whatever may be the merits of the practice proposed, it will doubtless be able to show sufficient to convince many that there are cases where that which they have hitherto denounced may be advantageously adopted by both landowner and occupier.

Upon these grounds—*i. e.*, in the hope of modifying a restriction which, when carried out without due discrimination, seriously retards the progress of agricultural improvements—we hold, that the general merits of the proposed system are worthy of special investigation.

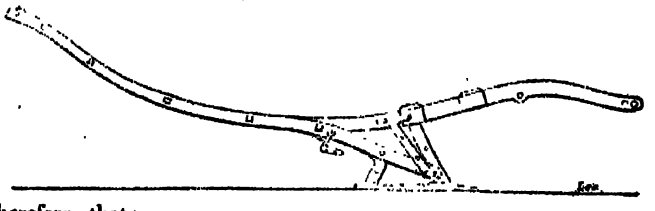
To this inquiry we now proceed. In estimating the merits of any system of husbandry, it is essential to ascertain:—1st. The amount of *profit* arising from it—*i. e.* the balance left in the hands of the cultivator after the expenses of cultivation have been paid; 2d. The gross amount or value of the produce raised from the soil—*i. e.* its quantity and value without reference to its cost; 3d. The amount of employment it has given—*i. e.* the *proportion* of the expenses of cultivation absorbed in cost of labour—the gross sum which it has invested in employment. On the first blush of the question, it may appear that the *first* is the only important consideration, as upon the profits of cultivation depend the landowner's rent and the interest of the farmer's skill and capital. No matter, therefore, according to this view, what may be the *quantity* produced, or what may be the expense of labour; so long as the balance is sufficient, the system is a good one. It is true that the *profit* of cultivation, whether it arises from a large gross produce, or a small cost of production, is the first matter to be considered—upon this both the owner and cultivator depend—and if there were no other interests vested in the soil, it would justly engage our whole attention. The time, however, has gone by when a man can say that he has an *exclusive* right in landed property. He has the first claim upon it, because his capital is sunk in it; and, similarly, the tenant, according to his proportion of capital; but no further. Property has, it is acknowledged, its duties as well as its rights. "No man," said a late and lamented nobleman, "has a right to do wrong with his own." So in the cultivation of land we must not consider any system worthy of our acceptation, solely because it is a profitable one to the cultivator, and through him to the owner. Though the owner have the main interest in the soil, the country at large has also a claim upon it. If the owner have capital buried in it, the country affords that capital the protection of the law, secures it against all foreign or domestic interference, and in fact gives it a *convertible* and *actual* value. Capital would be useless lumber were it not that the wants of an industrious population afford a ready exchange for its produce. And, lastly, the soil is one portion of what constitutes "England," and it is incumbent upon each *part* of any body, to act so as to aid and benefit the *whole*. It cannot, however, require argument to show that *English soil* ought to minister as far as possible to the wants of *Englishmen*, or that a *duty* devolves on property, which cannot be shaken off or commuted—a duty to produce as *much* as possible for the benefit of those whose demand confers a value upon what would otherwise be valueless, and by whose constitutional union the proceeds are secured to their owner. Allowing, therefore, that the country has some right in the soil, and that its claim for as full a supply as possible of the necessaries of life is a valid one, it will be evident that the second question must be answered satisfactorily—and the quantity of produce as well as the net profit arising from any system of management, must be taken into consideration in estimating its value.

The next question—that of labour—depends on the grounds urged in the above case. If a country has a claim in the soil, every individual has also an interest in it. Individuals constitute a nation, and in its interests they have individually a share. "This, however," it will be said, "does not prevent us from producing *cheaply*. If we give you *quantity*, we do our duty to the country at large and to individuals; after that we surely have a right to make as good a balance for ourselves as possible." Undoubtedly; but before we balance our accounts we should pay all our liabilities; and one of these is to provide labour for the labourer: he has a right to demand this on the clearest grounds. If the nation has an *acquired* claim upon property from the fact of the benefits it has conferred on that property, the labourer has a stronger *natural* one, the title to which is patent to every well-informed conscience. This claim—the right to labour—is his inheritance,—it is, in fact, his *capital*, a profitable field for the investment of which he may rightly claim as his due. When, therefore, the rich man invests *his* capital in the soil, he does it with the knowledge that there is a mortgage upon it, and it is his duty in the first instance to satisfy the original creditor.* No system of cultivation, therefore, can be a good one, which neglects to provide employment for the labourer, but which obtains its profits from the interest which is due to him.†

But it is not merely on moral and equitable grounds that we are bound to look at the labour required by a method of cultivation before we can estimate its value—on *national grounds* the amount of employment *we* can give is of the utmost importance; the exigencies of a vast and increasing population can only be supplied by allowing the healthy and the able labourer to invest the only capital of which he is possessed—his physical energy. Of what avail will be the produce of a *great quantity* of food if we do not provide an *equal quantity* of employment to enable the labourer to obtain that food? For these reasons, therefore, we maintain that the merits of any system of cultivation depend not merely on *the profit to the cultivator and the quantity of food* which it produces, but also on *the quantity of employment it provides for the labourer.*

We shall next week test the merits of the arable and pasture system by these principles.—*H.*

* We need not here rest our case merely on moral grounds; the poor man has a legal right to maintenance by the land, as the rich will soon find who, by refusing him permission to work for it, makes him a pauper.



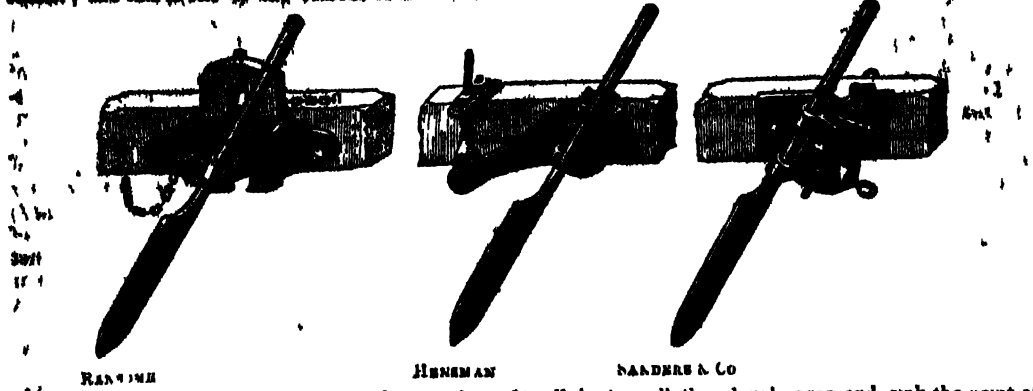
† See Professor Henslow's admirable letters on this subject, in the Suffolk papers of last month.

THE PLOUGH.

(*Continued from page* 802.)

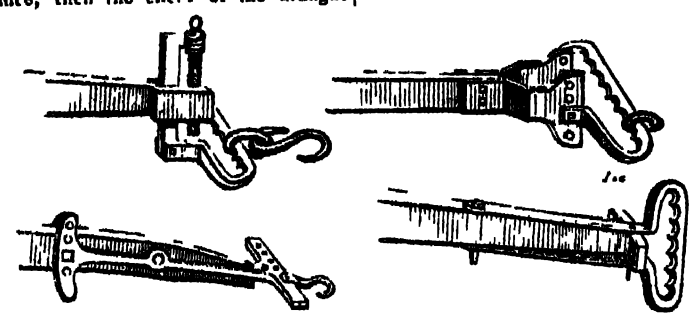
THE frame-work of the plough must be regulated by the work to be done, so far as strength to sustain the tear and wear and the shocks of the roughest work is considered; but its dimensions, the length of the beam and the length of the stilts or handles, as they only affect or regulate the power which the man or the horse has over the implement, need not vary with the work to be performed. These are wholly independent of the consistence of the land to be ploughed, or of the form of the furrow-slice, which both vary, and their dimension may therefore be fixed; and amidst the immense variety of forms of the plough, it is satisfactory to know that this point, one so much affecting the appearance of the implement, need not vary. The length of the beam in some degree affects the power of the horse over the implement. If it be long, the straightness of the furrow evidently will be less affected by any oscillating deviations of the horse from the straight path, and the motion of the implement will be more regular. This, however, is as well insured by lengthening the draught-chain as by lengthening the beam. The longer the handles of the plough, and the shorter the beam in proportion, the more power will the man have over his implement. There are, however, limits to both of these points, which convenience in the length of the implement impose. Very excellent dimensions are those of the Scotch ploughs of Clarke and Fergusson, plough-makers of Stirlingshire (see woodcut). The length of the beam is in these ploughs 3 feet, and that of the handles is 5½ feet; that of the whole plough is 10½ feet, which leaves 21 inches for that part of the frame-work to which the body of the plough is attached.

The following is a sketch of the mere frame-work of their plough, on a scale of 1-36th:—



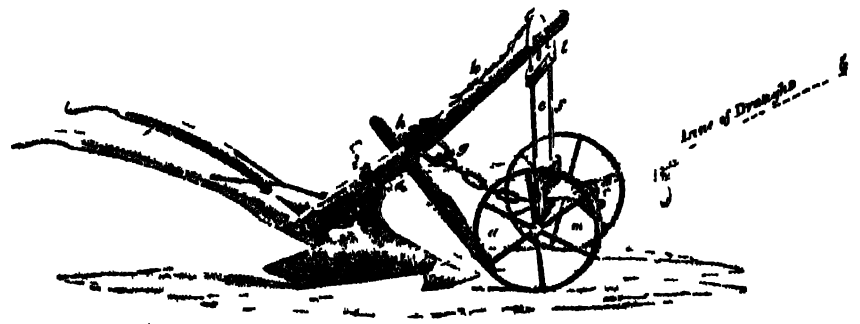
[Frame-work of Clarke's Plough. Scale 1-36th.]

The cutting parts of the plough are the share, which cuts horizontally the bottom of the slice, and the coulter, which cuts it vertically from the fast land, of which it forms part. It is evident that these should cut it perfectly. There should be no tearing when the mould-board begins to work. Any tearing must require an otherwise unnecessary exertion of power, and will increase the draught. In some districts an invention has been tried which does away altogether with the attachment of the coulter to the beam of the plough, and provides in its place a projecting edge, standing up from the sock on the vertical plane of the side of the plough, but inclining backwards towards the plough, at a considerable angle. This, of course, insured the perfect cutting of the sod; but it was found in practice that it encountered more obstruction, and was more liable to bend, or, if made of cast-metal, to break, than the common arrangement for the purpose: it was, therefore, abandoned. The relative position of the share and the coulter must, as we have already said, be such that they may cut a square-cornered sod. With regard to their actual position in the plough, it is obvious that the more inclined they are to their work, the more easily will it be accomplished. The cut will be more gradual—less abrupt. They should, therefore, be as much inclined to their work as is consistent with a convenient form of the plough.



Now, it is evident that, though it may be necessary, when altering the dimensions of your furrow-slice, making the plough go deeper or shallower, or when going from one description of soil to another, as from a clayey to a strong soil, to alter the position of the share or of the coulter; yet there can, under no circumstances, be any necessity for an alteration in the form of those parts of the plough. Here, then, is another part of the

plough which may be employed. We shall find that of all the parts of the plough, the mould board alone will require to vary with the work to be done. There should, however, be a means of altering the position of the coulter, and this is one of the reasons of the failure of that which, as I have said, has been tried instead of it. Besides the common excellent method of effecting this by means of wedges, the subjoined are figures of three methods of doing this, adopted by various agricultural implement-makers in England:—



RANSOME HENSMAN SANDERS & CO

There are other means of regulating the position of the plough, according to the nature of its work, which should, perhaps, have been mentioned when the frame work of the plough was described. It is evident that the line drawn from the horses' shoulders, through the point of attachment of the draught-chains to the plough, must, if lengthened, pass through the centre of the resistance met with by the plough at work. Should it be otherwise—should the line so lengthened strike the mould-board at a point higher, for instance, than the centre of resistance, then the effect of the draught will be to pull the plough over, and sink the point of the share, till the implement, by increasing the depth of the land ploughed, has raised the centre of resistance higher up the mould board. Should it strike the mould board to the right or left of this centre, then the plough in the same manner, in order that this centre may be brought into the line of draught, will be forced to take a greater or less width of land. This is the way in which the means act which are adopted for altering the dimensions of the furrow-slice.

The bridle of the plough admits of the attachment of the draught chain to the plough being shifted to the right or left; and so it enables the ploughman to increase or diminish the width of his furrow, and the bridle, by means of a screw or otherwise (see annexed figures), may be elevated or depressed, and so the depth of the furrow may be increased or diminished. There is another and very simple way of altering the depth to which the plough runs, and this is by changing the position of the back band. It has been before seen that by the action of this part of the harness a portion of the draught is thrown on the back of the horse, and only a portion of it remains on its shoulders. By shifting the back band nearer to the plough, we increase the ascent of the line of draught and of course tend to raise the point of the plough, make it work shallower, and by placing it nearer the shoulders of the animal, the plough is allowed to go deeper.

From what has been said it is evident that the object of the beam of the plough is merely to furnish a rigid attachment of the draught chain to the implement. The centre of resistance on the surface of the mould-board is a given point—so also is the attachment of the draught chain to the hames at the horse's shoulder—the straight line between these is the line of draught, and the beam of the plough must be extended in front at such a height and to such a length as may be necessary to afford an attachment of the draught chains, in this line, to a rigid part of the implement above ground and out of the way of the coulter. This beam may be made, if such be the will of the farmer as high and complicated an affair as he pleases, provided only some rigid part of it be found in the line of draught before alluded to as a place of attachment for the draught chains. Of course the simplest form of beam, which will answer this purpose, is the best. All this is well illustrated in the subjoined figure, for which we have again to acknowledge the kind loan of Mr. Allen Ransome.

Any remarks on wheel or swing ploughs should be made here, but the subject is, as I believe, comparatively of little importance. The wheel was, doubtless added by those who thought it an improvement, and it probably compensated for their unskilfulness in its management, making, in fact, the implement manageable by boys instead of men. And this is a fair and influential consideration in favour of the wheel, but it is not likely to induce its adoption in districts where the swing plough is already in use, and where the skill necessary for its management already exists.—*M. S.*

EXPERIMENTS ON NUTRITION.

I do not venture to express an opinion on the rival theories of eminent chemists, on the question, *for instance*, Is the fat of animals derived from the ready-formed constituents of their food, or from fat previously existing in such food? I only hope that they will very soon lay their heads together and tell us, from repeated experiments what really is the fact, and whether fat already formed does actually exist in the food in the large proportion which the French chemists assert. The experiments of Boussingault, given in this Journal, Nov 23, are certainly of the kind calculated to bear strongly on the point, and it is, indeed, such as those that we should rejoice to see performed and repeated in every possible way, by the chemist of the Royal Agricultural Society of England, with the assistance of one or more practical feeders, and under the auspices of the Council of our National Society. Which intelligent member would begrudge one or two hundred pounds so expended? We could readily suggest a mode by which this amount could be saved or obtained, if the present income of the Society should not be sufficient. But, with regard to the experiments in question, though we hail them as important additions to our magazine of facts, and agree with one of the inferences drawn by the experimenter that Mangold Wurzel and Potatoes alone are an insufficient diet for milch cows—which, by the bye, we should have anticipated—and also that a diet may be insufficient from the absence or deficiency of either of the three constituents mentioned by Boussingault (provided his facts are correct), yet we are constrained to observe, that his experiments fail to establish what they are intended to prove. We find that both cows are taken from a hay diet, and put entirely on Mangold Wurzel, a diet not only entirely different from that to which the digestive organs of the cows had previously been accustomed, but one consisting of 90 per cent of water, and deficient in woody fibre, which is essential for the proper performance of the digestive functions, and more particularly required to give firmness to the stercal, in order to fit it for ruminution. Such a diet, we hesitate not to assert, is calculated to derange the digestive organs, and interrupt the proper performance of their functions; and when this is the case, we may look in vain for the results which would otherwise occur. That this was the case the result proved, for the cows, we are told, were greatly emaciated—a result, putting chemistry out of the question, which no one can feel surprised at. And as this debilitated state was gradually induced, the digestive organs must have been gradually weakened, and must have failed in extracting the same amount of nourishment as before. The experimenter appears to have regarded animals as mere machines, and to have looked to chemistry alone, forgetting altogether that there was such a science as physiology in existence. Suppose that, in order to test the nutritious qualities of grain, we were to keep a horse entirely on Beans, what would be the result? Why, the animal would soon become emaciated and diseased, or if Oatmeal alone constituted the food, purging and debility would quickly supervene. Even if Oats alone were given whole, in which case the husk would, to a certain extent, counteract the laxative qualities of the meal, the horse would still lose flesh though an unlimited quantity of grain were afforded. To these facts the chemist will, perhaps, reply, "Oh! they only show that these different articles of food are deficient in some constituent necessary for the support of the animal." This may be true to a certain extent, but to a certain extent alone; for it is by no means sufficient that the food should contain the elements required for nourishing the body, but they must also be arranged in that peculiar manner and proportion which the structure and economy of the animal requires. If this were not the case, the excrements of the body would be proper for food, seeing that they contain the necessary elements of nutrition. The natural pasturage of the field either in its crude or prepared state, appears to be almost the only food that can be taken by animals with advantage, unmixed with any other diet. But then we must bear in mind that it consists of a variety of plants, and it is not only chemically sufficient for nutrition, but it contains that amount of woody fibre essential for the function of digestion, though not entering into the system itself. Thus herbivorous animals, having very capacious digestive organs, require their food to be of a bulky form, and of such a consistence that it will stay long enough in the body for the elements of nutrition to be properly extracted from it. Now it appears to us that M. Boussingault would have accomplished the purpose he sought to obtain by his experiment—*i. e.* the discovery of truth—far better if he had, instead of confining his cows entirely to roots, given a certain amount, or as much as they pleased to eat, of hay or good sweet straw at the same time. The health of the cows would thus have been preserved, and as the quantity of dry food could have been readily ascertained, its analysis being known, not only would the facts sought for by M. Boussingault have been discovered, but the relative value of Mangold Wurzel as food for milch cows would have been ascertained, which assuredly has not been done by the experiments referred to. We must, as we have before observed, leave the conflicting theories, as to whether the fat of animals is derived from any other elements than the fatty matters already formed in vegetables, to Messrs. Boussingault, Dumas, Liebig, and Playfair, simply observing that we shall not at all be surprised to find that the truth will be found to lie somewhere between the two conflicting opinions. One fact, however, we must mention, and it is somewhat opposed to the theories of the two former chemists. We are all acquainted with the fattening qualities of Barleymeal, particularly for pigs; we know that it is greatly superior to Oatmeal, and, indeed, any other food. Now if we turn to the analytical tables of Mr. Johnston we find that Oats contain 5·6 per cent. of fatty matter, whilst Barley only possesses 2·5 per cent. Now this certainly militates strongly against the opinions of the French chemists; and although we are at once ready to concede that the fatty matter in the vegetable becomes fatty matter in the animal, yet we are disposed to ask, Whence can the superior fattening properties of Barley be derived, unless it be the starch, gum, and sugar, of which there are 10 per cent. more in Barley than in Oats; the former having 60 per cent. and the latter only 50 per cent? With these observations we leave the subject for the present, observing in conclusion, that we do hope that under the direction and by the assistance of the Royal Agricultural Society of England, a number of experiments will be instituted in order to decide the many difficult questions relating to the feeding and fattening of animals, and the nutritive qualities of various articles of food. Private experiments entail more trouble and expense than private individuals are able to devote to the subject, and when they are published they do not appear with the sanction of authority.—*H. C. Spooner, Southampton.*

TREATMENT OF FARM HORSES AND LIVE STOCK.

Ask a farmer if he prefers for his own use a clean dry bed to a wet and rotten dung-heap? Ask him if cleanliness in place and person, with proper ventilation, is not conducive to his health? Ask him if his food, nicely cooked and prepared, is not more agreeable to him than if raw and dirty? Ask him if he likes cool residence in summer and a warm one in winter? He will say, certainly, and laugh at you in the bargain, and yet he will not consider, that what is good and agreeable

for himself, is quite as much so for his cattle. What would farmers say, if, after a hard day's work, they were obliged to walk ten miles for a supper, and the same next morning for breakfast—losing six hours' rest, and adding 20 per cent. to their labour? and yet this is how they treat their horses daily. It seems too ridiculous to be reiterated. I object entirely to turning horses out to have pasture at all; in our midland and southern districts, the waste of food and manure is enormous. If a horse is turned out 30 days on an acre, it is equal to 30 horses one day, or 40 horses half a day. Imagine what they must destroy—their weight crushes and injures an amazing quantity of food. It may be said, "Oh, the blades rise again next morning." Yes, but with this constant treading do they grow as fast and as luxuriant as if allowed to remain undisturbed and erect?—a foot-path or rabbit-run in a Grass-field will convince you. Then, where the droppings are, the food is lost; supposing the droppings and urine to cover and taint four square yards per day, that is 130 per month, or 3 per cent. per month. It is, in fact, 36*l.* lost in every 100*l.* per annum. The only excuse for depasturing is the imperfect state of the farm-yard, which allows the best part of the manure to be wasted.

Again, as to manure, there it lies in hot sunshine and bleaching winds, till it almost becomes its original straw-colour, losing its ammonia and other gases; and what, perhaps, is of more consequence than all, deprived of the benefits of fermentation which it would receive in a well-arranged tank. Supposing a horse's liquid and solid manure to be 1 cwt. per day, or 18 tons per annum, we lose one-third that quantity. In fact, it is not too much to say, that in the amount of labour the horse performs, his keep and manure, we can, by manger-feeding on my principle, save 30*l.* or 40*l.* out of every 100*l.* This is enormous!

Well may our great manufacturers, who consider a difference of 1 per cent. a good profit, exclaim against the want of calculation and management in farmers. Sincere friend as I am to the agriculturists, I admit, with shame, they deserve the censure bestowed on them in this respect. I call upon them to make at once honourable amends, by adopting my plan, and so save their money and their reputation. The idea of a man having 40 horses, costing him 1500*l.* per annum, and refusing to save 400*l.* or 500*l.* per annum in their keep, manure, and labour, is absurd; it is paying preposterously for the maintenance of prejudice or obstinacy, and yet, I am afraid there are some who will do so rather than act on my suggestions. There are other inconveniences and dangers attending depasturing horses—frequent kicks and accidents, loss of time in catching them, broken knees in driving home, and injury to constitution by sudden atmospheric changes. Besides, no horses fed entirely on green food can undergo the labour of those manger-fed on mixed food. Green food does not afford sufficient material for muscle and bone. It is too washy. I object *in toto* to permanent pasture, as a positive individual and national loss. Clovers are useful—but you cannot thoroughly hoe and clean the land when they are sown with a Corn-crop. Lucerne (and Sainfoin) is my favourite, and you can grow it anywhere* if you keep it clean, supply it amply with lime and its constituent parts, drain very deep (not less than 5 or 6 feet), and protect it from frost in the winter by a strong coating of manure, with a dust of guano in summer. Tares on heavy land, and Rye on light land, are both profitable; and plenty of Potatoes, Swedes, Carrots, &c., which can be grown on any land, however heavy, boggy, sandy, or gravelly, if thoroughly drained, properly manured, and deeply cultivated. By these means you may keep more than twice as much stock as by permanent Grass.

Were we to treat our bullocks and our sheep as we do ourselves and our riding-horses—keep them clean, warm, dry, and well fed—we should strangely increase the quantity and quality of our animal food.

Let us imagine ourselves standing or lying day and night for months in the moisture and effluvia of our own accumulated excrements, uncleaned and ill fed; it won't bear thinking of, and yet this is how most farmers treat their cattle: their food is presented to them in large unmanageable masses, with abundance of dirt (a corrector of acid it is called) uncooked and unprepared. We need not wonder at having to stab our bullocks to let out the accumulation of windy flatulence, or forcing strange-looking machines down their throats to remove solid lumps of unmasticated roots; we need not wonder at foot-rot, fevered feet, or other complaints. I will lay it down as an indisputable fact, as proved by our greatest breeders of animals, that we must apply to them the same treatment as we would to ourselves, if we wish to render them profitable. It is high time we amended our absurdities in this respect, or we shall have Spain, Portugal, and other warm and genial climes stocking us with what we ought to produce ourselves. Let us keep them warm in winter and cool in summer—free from tormenting flies. In fact, I shall never consider we are perfect till we can keep up a given warmth in winter—whilst we have in summer cool and shaded paved yards.
—*I. J., Meabi, 4, Leadenhall-street.*

(*To be continued.*)

ON MINERAL AND INORGANIC MANURES.

No. XXX.

By Professor Charles Sprengel.

(*Continued from page* 803.)

e. Ashes of Corn-stubbles.—If fields on which grain has been grown be ploughed shallow, and then harrowed, the stubbles, roots of weeds, &c., are brought to the surface; they are then raked together, and burnt in heaps, and the ashes strewed about. These ashes do not possess any particular value, as may be seen from analyses of straw, previously stated; their quantity also is so inconsiderable, that they are not worth attention. In the south, where they want less straw, the stubbles are left several feet high, and afterwards burnt on the spot. In this case the advantage is derived from the heating of the soil, and the destruction of vermin, as the value of these ashes as a manure is very trifling; 100 lbs. straw yield, at an average, only 4 lbs. of ashes, the half of which (as we have seen before) consists of silica.

f. Ashes of Brown Coal.—Pure brown coal yields ashes, which, according to all experience, are but poor manure. The reason is, that they consist merely of silica, alumina, and oxides of iron, and that most soils contain of these substances as much as crops ever require. As the ashes of pure brown coal contain neither potash, soda, chlorine, nor lime, magnesia, sulphuric and phosphoric acid, this may serve us as a proof that the fertilising properties of inorganic substances chiefly depend on the just-named seven substances. At times, however, brown coals contain sulphuret of iron, and whenever this is the case, they will yield ashes, which (if applied in proper quantity) are a very superior manure; because the sulphuret of iron will soon be changed into sulphate of iron, which, as we shall see presently, acts like gypsum. How many pounds are to be used per acre, experience only or chemical analysis can tell, as this depends upon their quantity of sulphate of iron, which varies. In Belgium, and other countries, 1000 lbs. to 1200 lbs. are strewed on one acre, which would indicate that it cannot contain much of the last, as 50 lbs. to 60 lbs. of that substance are an abundant manure for one acre of land. It is possible, however, that these ashes contain, besides sulphate already formed, also a considerable amount of sulphuret of iron, which would improve the soil for several years, as the changing of the latter substance into the sulphate takes place gradually. In the above countries, ashes of brown coal are used for manuring Rape, Clover, &c., the results being always most satisfactory.

g. Ashes of Coal.—Although the ashes of coal consist generally only of silica, alumina, and oxide of iron, still some are found which contain a little carbonate of lime, sulphate of potash, gypsum, and sulphate of iron. In the latter case, they are always a powerful manure; whilst, if merely composed of the three former substances, they are quite valueless, unless the protoxide of iron were to form ammonia, which, however, is yet to be ascertained by experiment. In the duchy of Luxembourg and on the Rhine, ashes of coal are used, with the very best result, for the rearing of Flax, Peas, Clovers, Beans, and Rape; they bear 1000 to 1200 lbs. on the acre, whence it may appear that these ashes contain gypsum or sulphate of iron. Both the ashes of coal and brown coal will also yield a superior manure for meadows, if they contain these salts. In Belgium, the ashes of coal and brown coal are often mixed with pig manure, and the compound is strewed over Clover, &c., which, as a matter of course, succeeds admirably. By using considerable quantities of coal, or brown coal ashes, though they contain neither sulphuret nor sulphate of iron, stiff clayey soils may be improved physically in a considerable degree: they are thereby loosened. It is still more important, that by a great amount of ashes, which contain much of these salts, the deep-rooted weeds may be destroyed, if the ashes be ploughed under to the depth of 16 or 18 inches. After the use of coal, or brown coal ashes, containing sulphate of iron, many sorts of vermin, especially snails, will disappear.

* Some regard, however, must be had to climate; I suppose our northern districts and hills are hardly mild enough for such productions.

Home Correspondence.

Tottenham Garden Allotment Society.—I send you a copy of the second half-yearly Report of the Committee of this Society, to deal with as you may think proper. In a late Number of your Paper is an article on the Allotment system, by "E. G. H.," referring more particularly to the Bill of the Honourable William Cowper, laid before Parliament towards the close of the last session, copies of which are now on sale at Hansard's, Great Turnstile, at 2*d.* each. I mention this circumstance, imagining that many who read your Paper may be anxious to procure a copy. "E. G. H.," after several common-place, ill-natured observations, such as "hoping the Bill may remain on the table of the House for ever"—"subject not adapted for legislation"—"proposition, if carried, will strike a death-blow at the system"—"labourers have their full share of mother-wit and suspicion"—"whatever we propose for bettering their condition must, on its very outface, display the absence of self-interested motives, or the labourers will attempt to defeat us"—then gives his own not very charitable interpretation of the Bill: "Now it appears to me, that this Bill of Mr. Cowper's, on the face of it, provides a very fertile source of such suspicion, for it proposes to enact, that any surplus arising after the discharge of all expenses shall be paid over to the overseer, in aid of the poor-rates," and refers to sec. 25, for proof of his assertion. Now "E. G. H." ought to have known, that it proposes that the field-garden wardens shall have power to take land belonging to any parish, or to the churchwardens and overseer, or guardians of the poor, or to the poor of each such parish (sec. 9), *the rent* of which land when let to the labouring poor (the Bill provides) shall, after payment of expenses, be paid over to the overseers, in aid of the poor-rates; and if there should at any time be a surplus from the other sources of rent specified in the Bill, which is not probable, the same also is to go in aid of the poor-rates. Now, if such surplus rents are not to be paid over to the overseers, to whom does "E. G. H." think they ought to be paid? or would he have the land let to a few poor persons free of rent, to the prejudice of the many? Then "E. G. H." has an illiberal fling at committees and committees, sub-committees, treasurers, secretaries, and collectors in general, just as if Mr. Cowper's Bill proposed to have one or all of these officials. Mr. Cowper's Bill does not provide for the services of either the one or the other of them. And now for "E. G. H.'s" grand panacea:—"The best method of getting the system into general action, is to leave it as free and unfettered as possible; let it spring from the spontaneous desire on the part of the owners of property, whether lay or clerical, to benefit their poorer neighbours according to their own knowledge of their wants and the best means of applying it, without the interference of rate-payers or any officials whatever." Now, let me ask, does Mr. Cowper's Bill interfere with that freedom? Mr. Cowper's Bill is an enabling measure, and not compulsory in any case, leaving to the majority of landowners and occupiers, in each parish or place, the power of adopting the measure or not as they may think proper; and when adopted, the landowners and occupiers rated above 10*l.* a-year to the poor are to choose two of the wardens; and the owners and occupiers of houses rated below 10*l.* a-year are to choose the other two, the resident minister being ex-officio the fifth warden, than which a more equitable mode of appointment it is impossible to imagine. At last we do get a bit of common sense, and "E. G. H." shall have the full benefit of it:—"The best method for insuring good cultivation, is affixing a rent which, *primâ facie*, may appear rather a high one, but which (when it is borne in mind that allotments are small, and all good land, generally near to the occupier's residence; and that there is no averaging of good and bad land, of long and short distances, for expense of cultivation; and that, as is well known, under the spade, land will throw out an enormously increased produce) will only appear to be a fair remuneration for expenses incurred, and accommodation afforded, while it tends to insure active exertion in their cultivation." So far so good; but alas! our differences are not all over. "E. G. H." would give none of the advantages of the system to any but persons of known good character and conduct; I, on the contrary, would not exclude any, good or bad; and the Society formed in this parish act on that principle, and with the best results, as the following *illustration* will show:—A gentleman at the head of the Temperance movement in this parish, and who is also a member of the Garden Allotment Society, at the last half-yearly meeting of the Society in the gardens said, he had tried every method to induce a certain person (naming him) to give up his drunken habits, but in vain; he had not seen him lately—indeed, for several months he had lost sight of him altogether. I observed—"Do you see that man carrying a watering-pot?" at the same time pointing towards him. "Oh yes," said he; "that is the man." I replied, "That man is earlier and later, and more constantly at work on his allotment than any tenant we have; and I have never once seen him, since he has been here, the worse for liquor." The gentleman, reflecting for a moment, exclaimed, "Yes, yes, that is the true cure; it is clear the man wanted employment for his leisure hours;" and then, in his usual good-natured manner, smilingly added, "Henceforth let us work together: I will continue to give them good advice, and do you find them pleasureable and profitable employment, and a great moral improvement is sure to follow." Before I conclude I will just remind "E. G. H." that he might have given Mr. Cowper credit for important matters which his Bill contains, besides those referred to, viz., that of enabling trustees and others who have or who may hereafter let land in small allotments to the labouring poor, to recover the rent and also regain the possession of the land by a summary process, instead of by the round-about expensive way in which either could now be obtained, especially since the passing of Lord Brougham's non-imprisonment Bill for small sums. In illustration, I will just state shortly a case, in which I was some time since engaged as surveyor, to show what allotment tenants may do, if disposed to set their landlords at defiance. A close of land of eleven acres was, some years since, divided into 88 gardens, the rent 1*s.* per pole, or 8*l.* per acre; three acres of this land were lately required for the site of a church, for which 500*l.* per acre was to have been paid; the owner was about to give the usual notice to the tenants to quit their gardens; they combined and resisted; their claims for compensation were so enormously high that it became necessary to abandon the treaty, nor could the Archbishop of York nor the church-building Commissioners assist us, and to this day have the tenants retained the possession of the land. To oust them would cost nearly the fee-simple of the close, as 88 actions of ejectment would have to be brought, with the certainty of the landlord's having to pay the costs on both sides, on account of the poverty of the tenants, and hence the unwillingness of many landowners to let their land in garden allotments. This evil Mr. Cowper's Bill will remedy, by providing a summary process in both cases to meet the evils complained of. I have now had twenty years' experience extensively in the management of allotment gardens, and, notwithstanding the difficulties which I have had to encounter, I have found the good preponderate so much over the evil, that I have never for a moment regretted the money and time I have spent in assisting my excellent neighbours to extend the system. In this parish we have now more than 130

gardens, under the management partly of trustees and partly a committee, consisting of some of the wealthiest and most worthy of our parishioners, headed by the Rev. the Vicar, and the amount of good that has resulted from the adoption of the system no language can adequately describe.—*J. D., Twickenham, Nov.* 18. The following are extracts from the Report referred to:—"Your committee have not been unmindful of events connected with the allotment system that have taken place in and out of Parliament since the formation of this Society, confirming as they do in the fullest manner that which your committee never doubted, viz., that larger allotments than the labourer and his family can cultivate, without trespassing upon his paid labour, was an evil, and ought to be discouraged; and hence, in no case, ought any allotment to exceed one-fourth part of an acre. But your committee cannot agree with the declaration of a noble earl, lately published in the *Economist Journal*, that the allotment system, by giving partial employment to surplus labour at home, prevents emigration to the manufacturing districts, and therefore ought to be discouraged; because it is against reason and humanity that emigration should be forced upon the labouring poor whilst beneficial employment can be obtained at home, and only requires the assistance which an allotment garden will furnish to make them contented and happy."—"Your committee have seen with great pleasure a bill prepared by the Hon. Wm. Cowper and Wm. Miles, Esq., M.P., intituled 'A Bill to promote the letting of Field Gardens to the Labouring Poor,' the provisions of which appear admirably calculated to secure the object contemplated, viz., an extension of the garden allotment system upon just principles; to promote which your committee trust they shall have your approval, and the approbation of all the parishioners, to petitions proposed to be presented to both houses of Parliament in the next session, which the hon. secretary will prepare in favour of this Bill, under the superintendence of your committee."—*Jas. Dean, Hon. Sec.*

Irrigation.—Having read many of your articles on draining, and perceiving that great progress has been made and is still making in this process, I have been led to think it a pity that the opposite operation of irrigation could not receive some attention. It has occurred to me that these very drains might be turned to account in an attempt at introducing irrigation. I am no agriculturist, and have therefore to inquire if there is not sufficient water drawn off the field by these channels, which, if allowed to accumulate in a subterranean tank, might again, by simple and inexpensive machinery, be redistributed to the land during the droughts of summer. You could have the underground reservoir of any size; but, as I have already hinted, I fear the water collected during winter will be insufficient to counteract, to any great extent, the bad effects of dry weather.—*Anonymous.* [Probably, less water, under the same circumstances, runs off a field after being drained than before it was drained. The tendency of the operation is to cause all water that falls on it to pass *through* it, instead of running away *over* it. Drainage tends in various ways to the pulverisation of the soil, and thus makes it more retentive of moisture: well-drained land is rarely injured by drought; undrained land in dry weather cracks, and lets the dry air and heat into the very heart of the soil. Well-pulverised land, though of course, under the influence of heat, has the same tendency to contract and crack; but, the soil being loose, no cracks can appear; and thus the drought, acting only on the surface, is less injurious.]

Clover Dodder.—Absence from home having prevented me from reading some of the Numbers of the *Agricultural Gazette* until now, the Leader concerning Clover Dodder (p. 625) has only just met my eye. In it I find a statement that the seed of this destructive weed was probably introduced from Cabul with seed of Trefoil; and, as this observation is likely to mislead the readers of the *Gazette*, I think it right to state that the Dodder obtained from Cabul is a totally different species, the structure of its flowers being very different from that now destroying Clover in England. From rather extensive inquiries, I have every reason to believe that the Clover Dodder (*Cuscuta trifolii*, Bab.) is imported from the continent of Europe with the seed of Clover; but I have not been able to get such exact information as to prove it. I wish that the farmer would note down the day on which he buys his Clover-seed, and the name of the wholesale dealer from whom it is obtained; also its British or Foreign origin; and, in the latter case, learn, if he can, the country from which it is imported. When the Dodder occurs in the field, we shall know to what country to look for its origin, and may guard against it in future. In the spring I asked for similar information, but have obtained none. The Cabul Dodder is the *Cuscuta approximata* (Bab.), and both it and C. trifolii are quite different from the C. europæa, C. epithymum, and the Flax Dodder, C. epilinum.—*Charles C. Babington, St. John's College, Cambridge, Nov.* 30.

Linseed.—Seeing several communications on this subject in your Paper for the last five or six weeks, and not finding it anywhere stated that the Linseed can be ground by a common miller without any other than the usual stones employed by millers, if the miller adds an equal quantity of bran to the Linseed, I beg to apprise your readers of this fact, as some parties may be deterred from using this useful compound, by the supposition that they require a mill on purpose to crush the Linseed. I have fatted three bullocks on compound made of Beans and Linseed ground with bran at the mill, and found it answer very well, and the bullocks eat it with avidity; the proportions I used were three measures of Bean-meal to two of the Linseed-meal and bran when mixed, with water sufficient to make it into the consistence of stiff dough. I am now trying the compound made of Barley-straw chaff and cut Beet-leaves in the way mentioned by your correspondent in last Saturday's Paper, with my ponies and cows, and hope to send you the result of this kind of feeding with such stock. If it answers, it will tend to increase the manure heap, as the leaves of Turnips and Beet are very often left to rot in the fields, which is not the best way of making the most of them as a manure. If you think this worthy of insertion I shall have much pleasure in sending you it.—*T. E. W.*

Pigs.—I have a sow which had eight pigs; six of these I penned up by themselves in half of a cowshed to fatten, and they are doing very well. Two sow-pigs I kept with the mother for the purpose of breeding from: besides having a small piece of the cowhouse to themselves, they had a small square piece in the open air in front. As this open part was very damp, I tried to make asphalte of boiled tar and gravel, but the tar not having been boiled long enough remained soft, and over it some litter was spread. Having been away from home I was vexed to learn that one of my little sows had died in my absence, and on the morning after my arrival home I heard the other had been ailing some days—in fact the butcher put it out of its troubles before the day was over. Upon being opened the livers of both were found much inflamed, and the meat soon began to turn green. I ought to say that from the great rain we have had lately, the outside space of litter, tar, &c., was quite in a swamp, though their house was dry. Will you be so good as to tell me how to account for their deaths? Could it be the damp, or had the tar anything to do with it? as I purposed flooring a pig-stye with asphalte. I should say my brother tells me that he has lately lost three pigs of inflammation of the liver, and that his styes are dry; mine have been fed on oatmeal and wash. What is the best medicine for them?—*Northwood.* [We believe the disease in your pigs is to be attributed to the swampy place they were allowed to remain in. The tar could have had nothing to do with the matter. We do not think you have any reason to fear using asphalte for the floor of your pigstye, if properly prepared and allowed to get firm before it is made use of. With regard to a remedy for the disease of the liver, the following will be most likely to prove effectual:—Protochloride of mercury, 2 grains; powdered opium, 2 grains for a porker, and double the dose for a large pig. To be mixed in thick gruel and given once a day.—*W. C. S.*

Waste and Destruction of Fences.—Although a tenant from year to year is not bound to put premises in repair, he is not, on the other hand, at liberty to do anything which amounts to waste, or to a breach of the rules of good husbandry; he is not, therefore, entitled to cut and sell hedge-rows, or at least not without making up the hedges and fences according to the course of good husbandry. If there be a quickset fence of Whitethorn, if the tenant stub it up or suffer it to be destroyed, this is destruction; but cutting up quicksets is not waste, if it preserves the spring.—So decided in Gage v. Smith.—*A. Quiet Observer.*

Irrigation.—In this neighbourhood the usual method of irrigating meadows is to stop up every drain and to flood the land with water. Would it not be better to let every drain be open, so that the water might, as rapidly as possible, percolate through the soil? [Certainly]. Here also it is customary to let it remain on for some days; would it not be the best to allow it to remain on only for a short time, say 24 hours, and then let it get well drained before another application?—*A Leicestershire Farmer.* [The proper period depends upon the weather and time of the year].

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

A Monthly Council was held at the Society's House in Hanover-square, on Wednesday last, the 4th of December; present—His Grace the Duke of Richmond, President, in the chair; the Rt. Hon. Earl Spencer, Hon. Capt. Spencer; T. R. Barker, Esq.; S. Bennett, Esq.; J. F. Burke, Esq.; Col. Challoner; F. C. Cherry, Esq.; H. Gibbs, Esq.; B. T. B. Gibbs, Esq.; W. F. Hobbs, Esq.; W. H. Hyett, Esq.; J. Kinder, Esq.; H. Price, Esq.; P. Pusey, Esq., M.P.; F. Pym, Esq.; J. A. Ransome, Esq.; Prof. Sewell; W. Shaw, Esq., and J. V. Shelley, Esq.

The following new Members were elected:—

Alexander, Caledon, Rothamsted Park, St. Alban's, Herts.
Mathews, Richard, Esgir, Machynlleth, Aberystwith, S. W.
Buck, Lawrence, Pantlludw, Machynlleth, Aberystwith, S. W.
Whitcombe, John, Hay-Ugborough, Totnes, Devon.
Jolliffe, Colonel John Twyford, Ammerdown Park, Bath.
Donaldson, Thomas, Longlands, Eltham, Kent.
Lee, James, Noah's, 1, Little Charlotte-street, Blackfriars-road.
Bailey, Samuel, Westham, Kent.
Cox, Thomas, Parkfields, Derby.
Fountain, Henry, Lowfield, Burton, Linc.
Westcote, John Baker, Coate, Martock, Somerset.
Paine, Joseph, Ruthin, Denbighshire.
Lewis, Lieut. Richard, 3d Life Guards.
Underwood, Walter, Oakley, Bedford.
Harding, T. Goldie, Monkleigh, Torrington, Devon.
Turner, John Beresford, Brockmanton, Leominster, Hereford.
Rumney, George Hepple, Derwent Villa, Newcastle-on-Tyne.
Le Blanc, Arthur, Maresfield, Uckfield, Sussex.
Norris, John, Highandcot House, High Wycombe, Bucks.

The names of 15 candidates for election at the next meeting were then read.

Finances.—Mr. Raymond Barker, Chairman of the Finance Committee, read the Report of the Committee on the state of the funds of the Society at the end of the month last ended; from which it appeared, that the invested capital amounted to 7700*l.*, and the current cash balance in the hands of the bankers to 391*l.* He also laid before the Council the balance-sheet of the Southampton meeting, showing in detail the various items of receipt and expenditure connected with that account, the total amount of receipts (including the subscription from Southampton) being 4929*l.* 5*s.* 10*d.*, and the total payments 5786*l.* 5*s.* 2*d.*, leaving an excess of the payments over the receipts, on that occasion, of 856*l.* 19*s.* 4*d.* chargeable on the funds of the Society, in addition to the sum of 1358*l.* as the amount of Prizes only, awarded by the Society at that meeting.

Local Collectors.—The Council resolved, on the motion of Mr. Pym, seconded by Mr. Gibbs, that it was desirable that paid collectors should be appointed in counties or districts; and that the details of the system should be referred to a committee consisting of Mr. Pym, Mr. Shaw, Mr. Gibbs, and the Members of the Finance Committee; three of whom should form a quorum, with a request from the Council that in their report they would state the rate of remuneration recommended by them to be paid to the proposed collectors.

Lectures.—Mr. Pusey reported to the Council the arrangements already made for the delivery of lectures before the members at their ensuing Christmas meeting by Dr. Playfair, the consulting-chemist of the Society; when it was resolved that the lectures should take place on Wednesday, the 11th, and Thursday the 12th inst., at 9 o'clock in the evening; and that Professor Sewell, Mr. Gibbs, and Mr. Shaw, should be requested to act as a committee for engaging a suitable theatre for the delivery of the lectures, and the exhibition of the chemical experiments with which they were to be illustrated.

General Meeting.—The President announced his intention of directing a Special Council to be summoned for Saturday the 14th instant, at ten o'clock in the forenoon, for the purpose of taking into final consideration the Report of the Council to the General Meeting to be held at one o'clock on that day.

Lists of Members, Models, &c.—On the motion of Mr. Fisher Hobbs, seconded by Mr. Shaw, it was resolved that a list of the Members of the Society should be printed in a cheap form, and appended to the first half volume of the Journal for 1845, to appear about midsummer in that year. On the motion of Mr. Fisher Hobbs, it was resolved, that an Inventory, with an Index, should be prepared, of all Implements, Models, &c. in possession of the Society. On the motion of Mr. Fisher Hobbs, seconded by Earl Spencer, it was resolved, that a catalogue of the books in the Library should be made by a professional person to be engaged for that purpose, under the direction of the House Committee.

Judges of Stock.—On the motion of Mr. Fisher Hobbs, it was also resolved, that in future the Judges of Stock shall be appointed by the Council, from a list of nominations made by the members at large at a general meeting, and on the report of a committee to whom such list shall have been referred. On the motion of the Hon. Captain Spencer, seconded by Mr. Bennett, it was resolved, that, in the appointment of Judges of Stock, those names only shall be given to the Stewards of the yard determined by the Council for each breed; that in case one or more of those named shall not appear, a supplementary list of Judges shall also be given to the Stewards, who shall from such list fill up the vacancy.

Exhibition of Stock.—On the motion of the Hon. Captain Spencer, it was resolved, that after the awards of the Judges of cattle shall have been delivered to the Director of the yard by the several Stewards, such Members of the Council (not being exhibitors) whose duties for the Society prevent them from seeing the cattle when the public are admitted, who shall be named by the Council the month prior to the meeting, shall be admitted to view the cattle from 5 o'clock till 7 of the Wednesday, (provided the awards shall have been delivered;) but that the awards shall not be declared before the usual time, namely, after the Council dinner.—Mr. Bennett gave notice that he should move, at the next monthly Council, that herdsmen and shepherds, not being exhibitors themselves, or relatives of exhibitors, should be allowed to be in attendance on their stock, but on no account to remain in the show-yard when the Judges enter.

Trial of Implements.—Mr. Shaw having withdrawn his motion on Trials of Implements, distinct from those made at the time of the Annual Country Meeting, Mr. Shelley laid before the Council the joint report of Mr. Miles and himself, as Stewards of the Implement Department, on the communications of Mr. Clayton, Mr. Cousins, and Mr. Smart; and letters were received from Mr. Barnes and Mr. Graburn, on the trials respectively referred to them of Cultivators and Hand Corn Mills.

The Council having appointed the standing committee for the ensuing year, and agreed to the preliminary draft of Regulations for the Shrewsbury Meeting, submitted to them by Mr. Brandreth Gibbs, postponed the consideration of Mr. Gordon's offer of a Prize, and the communication from the British Association on the Analysis of Ashes of Plants, till the next Monthly Meeting. Communications were received from Mr. Jerdan, Secretary of the Border Agricultural Society; Mr. Mechi, Mrs. Welford, Mr. Dean, Mr. Evans, Mr. Moffat, Rev. S. Lysons, and Mr. Garnett.

The Council then adjourned to Wednesday next, the 11th of December.

FARMERS' CLUBS.

Chepstow.—[The following is an abridgment of a Report on the Farms competing in Monmouthshire for a Premium offered by John Buckle, Esq.] We wish to convince landlords that in no way can they do more towards improving their estates than by giving premiums for good cultivation. A tenant, occupying 200 or 300 acres of land, would be sure to lay out many times the value of the prize in preparing his farm for exhibition, with the hopes of obtaining such an honorary testimonial of agricultural skill; and, at the same time, this expense would benefit the candidate himself, inasmuch as good cultivation, provided the outlay be judicious, is always more profitable than slovenly farming. We would also wish to draw the attention of both landlords and tenants to the mutual advantages of leases, though we are decidedly of opinion that the only eligible form of lease must be founded on a corn-rent, and then it should be of such duration as would enable a good farmer to improve his farm to the utmost. No tenant, without a lease, can feel secure in investing capital in the permanent improvement of his farm. To commence with the cropping:—The quantity of Swedes and Turnips was more than one-fourth of the arable land on all the farms we visited, except two; and in these exceptions very little less than one-fourth was planted with these roots. In the case of the successful candidate, the proportion was much larger; he had nearly half his arable land under Swedes and Turnips. We found the general plan was to sow one-year-old Clover with Wheat at one ploughing. We saw some fallows, but the quantity was comparatively small. Where the Clover has been sown on foul land, which should never be the case, the only remedy is to fallow for Wheat. Part of the Turnip land is generally sown with Wheat; and the quantity of land under Barley was, in consequence, small. We found the Swedes and Turnips for the year very good, without exception, though of course superior on some farms to others; but we noticed a much greater difference in the cultivation than the weight of crop. We were sorry to see some good Swedes and Turnips that we could not consider clean, many acres not properly horse or hand-hoed, and nearly all those broadcast were far too thick; and we wish to lay particular stress upon the necessity of remedying this defect, as, on the four-field system, the only chance of cleaning the land is when under a root crop. We have this year seen land intended for Swedes made as clean as a garden by means of the Uley cultivator, first using the broad shares to pare off all the stubble; then the grubbers, till all the weeds were brought to the surface; and, lastly, all the rubbish was gathered together with a horse-rake, and carted into a heap to rot. The average proportion of land in Clover and Grass-seeds is about one-fourth, part of which is sown with the Wheat after a root crop. We were surprised and delighted to see many fields with a capital plant of Clover; and, in other instances, we had the mortification to witness a complete failure, which is to be attributed to the dryness of the spring and summer. We think that, by some alteration in the rotation, the quantity of Clover might be lessened, and the extent of root crops augmented, without reducing the proportion of Corn; thus avoiding so frequent a repetition of Clover. We do not at all mean to lay down an arbitrary course, to be followed for years without any deviation. In fact, we have known this done, and the plan materially altered in a few years. Still, we would suggest, on the light lands of this district, something like the following rotation:—

List of Crops for 200 acres of arable land.

First Year.			Second Year.		
5 acres	tankard Turnips				
10 „	Mangold Wurzel				
10 „	Carrots	30 acres Wheat

35 „	Barley		35 „		Clover.
35 „	Clover		35 „		ley Wheat.
200 acres.			200 acres.		

Without pursuing this course any further, it will be evident to every farmer that the crops may be varied so as not to repeat Clover, Swedes, and Turnips, so often as in the usual rotation. As regards the implements, with some few exceptions which we intend to mention, we only observed those in general use: viz., ploughs, old-fashioned drags, harrows, rollers, horse-hoes for Turnips, &c. Some of the land we noticed was too stony for scufflers or cultivators to be used profitably; but we saw much land where one of Lord Ducie's implements would be most valuable. Wherever the Uley cultivator can be used, the manner in which it will pare off the foul surface and bring all the couch-roots to the face of the ground is far superior to ploughing the weeds in. We observed that admirable implement for reducing rough land for Barley, Turnips, &c., Crosskill's clod-crusher, at Mr. John Dowle's, of Claypit; a horse gripping-plough, a hand ditto, and a mole-plough, at Mr. Thos. Perkins's of Matherne. We also noticed one of Finlayson's harrows, and a horse-hoe of simple construction, for hoeing Turnips when drilled on the flat; the latter was made to fix on to a part of light cart-wheels, and consisted of three shares, to take three rows at a time. The width between the shares could be altered, and narrower shares might be substituted, to fit it for hoeing Wheat. This hoe was made by a country blacksmith, at a very moderate price. These two last implements we saw at the house of Mr. B. Matthews, of Ifton Hill, who was not a candidate for Mr. Buckle's cup. The carts and waggons we saw were all of the heavier description, which certainly require to be replaced by others of a less cumbersome character; but, whenever this takes place, we are aware that the change must be gradual. The largest quantity of stock was rather less than two sheep to an acre, and one head of cattle to every five acres, taking the whole farm for both. On one farm we saw three sheep to each acre of arable land; but the proportion of meadow and pasture to the arable was as three to four, which reduces their number to our standard. In every instance the number of cart-horses was greater than we considered requisite, in all cases exceeding one pair to every 50 acres of arable land, which we should say was quite sufficient. The breed of horses for farm purposes in this district is generally bad. We found great cause to complain of the management of some of the hedges and headlands. In many places a belt of two or three feet wide was left uncultivated round the fields, full of Couch, Nettles, and other weeds. In but one instance did we perceive any attention paid to the land adjoining the fences, to prevent the weeds from seeding over the farm. We should like to see every inch of ground kept clean round the hedges, and all the weeds in them cut out two or three times in the course of the summer, to prevent them ripening their seeds. Many farmers may complain of the expense of this, but it would pay enormous interest in the saving of future labour. We recollect once seeing a fallow for Wheat which was very clean except a few roots of knotted Couch, all of which laid on the surface and were ploughed in. For 6*d.* an acre they might all have been picked off; and surely by its not being done a much larger expense was incurred in cleaning the land for Turnips. We sincerely wish the management of farm-yard manure were better attended to. We did not see a single tank to collect the drainings of the yards, stables, pigsties, &c. In some places the liquid manure escaped into the road and ditches: in others it was led into the nearest field, and when there, suffered to soak into the ground, only benefiting a very small spot; and, worst of all, some of the yards and buildings were allowed to drain into the pool where all the horses and cattle were taken to drink. The ammonia and other salts contained in this liquid are strong stimulants, and therefore liable to cause violent inflammatory disorders. We observed that lime is not used at all as a manure on the light lands we inspected, but we think a moderate quantity, applied once in a rotation, would pay well for the outlay. Chemical analysis teaches us that lime is contained in both the straw and grain of Wheat; in short, that there is only one plant yet discovered in which no trace of lime can be detected. We recommend all those who are opposed to the use of lime, to read some of the many scientific and practical articles on the subject that have been published lately in the agricultural periodicals, and can be obtained at our library by every member. The only complete set of farm buildings we met with was on the farm of Mr. Thos. Dowle, of Ifton (who for the cultivation of his Turnip land deserves unqualified praise), and they only require tanks to be everything a farmer could wish. The drains are all laid in readiness, and the tanks are to be added shortly. The buildings are mostly new, but not being quite completed, we consider they would be seen to much better advantage another year. The roofs are all covered with reed (combed straw) under the tiles, which keeps the buildings warmer in winter and cooler in summer than tiles alone. In giving our decision, we have no hesitation in awarding the prize to Mr. Thomas Perkins, of Matherne. He has a great breadth of his arable land under Swedes and Turnips, all clean, and the rest of his arable land in a better state of cultivation than the other competitors, though we think there is still room for improvement; and we wish all who read this paper to observe that we cannot consider a farm to be well cultivated because the tillage of some of the fields is good, but expect them to be all clean and in a high state of cultivation. It is in the management of his Grass land that Mr. Perkins so much excels, he having been at great expense in cleaning his fields from bushes, and laying down some miles of drains; besides which, he has cleared away all the banks formed by cleaning out the ditches. The soil he procures in this manner he mixes with farmyard manure or lime, and annually dresses a considerable portion of his Grass land. We will merely hint that we should like to see some cattle soiled all the year, with every particle of their manure preserved and taken out upon the land; and we think that any gentleman who wished to encourage improvement in farming, could not do better than to offer a premium for the largest number of cattle kept in houses and yards all the year round. R. W. Purchas, Hon. Sec. Mon. Farm. Club, and Arthur Hall, Hon. Sec. Chep. Farm. Club—*Judges.*

Debenham.—The fifth Annual Meeting of this Club was held on Friday last (Nov. 22, 1844), at the Cherry-tree Inn, in Debenham. Much interest was excited by the display of fruit and vegetables for the Cottagers' Prizes. Upwards of 200 different productions were exhibited by about 50 cottagers; market or working gardeners, persons whose rent exceeded 6*l.* per annum were excluded. The Prizes were awarded as follows:—

Three Silver Tea-spoons, given by the Rev. James and the Hon. Mrs. Hodingfeld, for the best cultivated Cottage-garden or Allotment in Debenham, were awarded to Robert List, on account of the great variety of his crops, proper rotation, and the extreme cleanliness of his allotment; this is the second prize of spoons obtained by List. *Best Dessert Apples*, 3*s.* to T. Smith, of Debenham; second do., 2*s.* to J. Jacobs, Debenham. *Best Kitchen Apples*, 3*s.* to W. Tydeman, Debenham; second do., 2*s.* to A. Brown, Debenham. *Best Dessert Pears*, 3*s.* to W. Rumsey, Debenham. *Best Baking Pears*, 3*s.* to J. Pallant, Debenham; second do., 2*s.* to J. Barrick, Debenham. *Best 12 Carrots*, 3*s.* to R. Aldous, Debenham; second do., 2*s.* to R. List, Debenham. *Best 12 Parsnips*, 3*s.* to R. Aldous, Debenham; second do., 2*s.* to J. Moyse, Winston. *Best* ½ peck of *Onions*, 3*s.* to R. Moore, Thorndon; second do., 2*s.* 6*d.* to R. Aldous, Debenham; third do., 2*s.* to J. Marjoram, Debenham. *Best* ½ peck of *Potato Onions*, 2*s.* 6*d.* to R. List, Debenham; second do., 1*s.* 6*d.* to W. Smith, Debenham. *Best 3 Savoy Cabbages*, 3*s.* to D. Blomfield, Little Stonham; second do., 2*s.* to R. List, Debenham. *Best Brussels Sprouts*, 2*s.* to G. Clarke, Earl Soham. *Best 6 Roots of Celery*, 3*s.* to D. Blomfield, Little Stonham; second do., 2*s.* to J. West, Stonham Aspal. *Best 3 Pumpkins*, 3*s.* to G. Skipping, Debenham; second do., 2*s.* to A. Read, Thorndon. *Best* ½ peck of *Early Potatoes*, 5*s.* to D. Blomfield, Little Stonham; second do., 4*s.* to J. Moyse, Winston; third do., 3*s.* to J. Keeble, Debenham; fourth do., 2*s.* 6*d.* to J. Wade, Debenham. *Best* ½ peck of *Late Potatoes*, 5*s.* to H. Sawyer, Debenham; second do., 4*s.* to R. List, Debenham; third do., 3*s.* to A. Read, Thorndon; fourth do., 2*s.* 6*d.* to R. Aldous, Debenham. *Best* ½ peck of *Kidney Potatoes*, 4*s.* to D. Blomfield, Little Stonham; second do., 2*s.* 6*d.* to R. List, Debenham. *Best* ½ peck of *Red Potatoes*, 4*s.* to R. List, Debenham; second do., 2*s.* 6*d.* to G. Smith, Debenham. EXTRA PRIZES: *Red Potatoes*, 2*s.* to J. Taylor, Debenham. *Onions*, 2*s.* 6*d.* to W. Smith, Debenham. *Late Potatoes*, 2*s.* 6*d.* to R. Aldous, Debenham. *Early Potatoes*, 2*s.* 6*d.* to R. List, Debenham. *Red Cabbages*, 2*s.* 6*d.* to J. West, Stonham Aspal.—*W. G., Hon. Sec.*

Reviews.

On Landed Property and the Economy of Estates: comprehending the relation of Landlord and Tenant, and the Principles and Forms of Leases, Farm Buildings, Enclosures, Drains, Embankments, Roads, and other Rural Works, Minerals, and Woods. By David Low, Esq., F.R.S.E., Professor of Agriculture in the University of Edinburgh, &c. Longman & Co.

THE last chapters of this valuable work are devoted to the explanation and illustration of practical details. Those connected with the erection of farm buildings, with drainage, roadmaking, plantations, &c., are all fully entered into, and admirably illustrated by woodcuts. These chapters render the volume especially useful to landlords, agents, and all who are engaged in the permanent improvement of estates.

But it is to the first chapters of Professor Low's work that we wish particularly to direct the attention of the reader. They contain an excellent exposition of the importance of the lease as an instrument of good or evil. The permanency which it gives to the tenants' interest in his farm is of course as injurious to the estate and community when it binds to the practice of bad farming, as it is beneficial to all parties when it is framed so as to insure the introduction and establishment of good husbandry. Much of the slowness of agricultural improvement is justly attributed to the want of confidence on the part of the farmer which is inseparable from the tenant-at-will system, which prevails in England to so large an extent:—

"To what are we to attribute this tardiness to adopt what is new and useful in an art which it would seem to be the interest of every one to improve to the uttermost? A part at least of the effect must be ascribed to the conditions under which the capital of the farm as compared with that invested in other branches of industry, can be employed. The manufacturer of cotton, of wool, of iron, has the assurance that the machine which he constructs and improves for the purposes of his trade is his own, and that the more perfect he can render it, the more profitable will the use of it become to him. The farmer who lays out capital on the great machine on which his all depends, the earth which he tills, has often no such assurance. It is the property of another, who in the end will profit by all the improvements which the skill of a temporary possessor can make upon it. The manufacturer receives, directly, the profits of his stock in trade; the farmer must share those profits with another, who undergoes no part of the labour and risk; his industry is fettered by conditions imposed upon no other class of traders; and the inconveniences of obtaining returns for a present expenditure more slowly than in any other profession, are frequently aggravated by the uncertainty whether he will ever have the power of recovering the capital advanced."

The following are the conditions required to establish fitting relations between the owners and occupiers of land:—

"1st, Security of possession; 2*d*, Equitable rents; 3d, Suitable conditions with respect to the methods of culture and general management; and 4th, an adequate provision by the landlord for the fixed capital invested in buildings, enclosures, and other necessary appendages of the farm."

On the second of these subjects Professor Low says:—

"The actual profit to be derived by the farmer should in every case bear a ratio to the capital employed by him. The lowest calculation that can be fairly made is 15 per cent. on the capital employed, out of which the farmer must support himself and bear the risks of his trade. The farmer, therefore, who takes land should calculate, in the first place, the fixed capital which he must advance. Allowing 15 per cent. for interest, the profits of stock, his own maintenance, and the risks of his trade, the remainder of the produce is left for expenses and the landlord's rent."

After remarks in which the difficulty of finding employment for capital, and the limited number of farms at any time in the market, are alluded to, in order to show that the tendency of rents is always to rise above the just level, the author observes:—

"It is difficult for a proprietor of land to take a perfectly impartial view of the value of that which he has so great an interest in rendering available as a source of income; but it should never be forgotten that every tenant must have such a profit as will enable him to maintain himself and cultivate his land, and insure him

against the contingencies of his trade. To take away the tenant's profit is to produce the inroad of trenching upon his capital, and to trench upon his capital is to lessen or cut off the source from which the landlord's rent must be derived."

The following passages just express the simple truth: they are worthy of serious attention:—

"It is common to hear of reductions of rent, as 10, 15, or 20 per cent. made by proprietors at their audit days, and announced in newspapers and otherwise as acts of great liberality. But bounties in this form are nearly useless to the tenant. The necessity, where it exists of making little abatements of this kind, should lead us to the conclusion that an estate is under bad management. The rent at which land is let should be such that no temporary bounties of this kind can be needed. The tenant who takes land, and the landlord who lets it, should so adjust the rent that the tenant shall be able to bear the pressure of deficient crops, or of low prices arising from favourable ones; and no prudent man ought to contract for a rent which will not allow him to meet that contingency of his trade which arises from a fluctuation in the amount and price of his commodities."

"*The landlord who would secure a prosperous tenantry, and improve his estate, must not trust to his percentage of bounty on an audit-day, but must place his tenants in the condition which will enable them to fulfil the obligations under which they engage in virtue of a fair and well considered covenant.*"

Besides these general remarks Professor Low enters in another chapter into that practical detail on the subject of "the lease" on which his long experience in these matters renders his statements worthy of our entire confidence, and his opinions worthy of much deference. The following is his opinion on the subject of rent:—

"Of rents of land, the most satisfactory, it is conceived, is a fixed payment in money. To rents payable in grain, or in money determined by the prices of grain, there is this objection, that the tenant may be required to pay the highest rent when he is least able to do so; that is when prices rise from deficient crops. In such a case if a tenant has not a good capital to support him, he may be injured in a single year beyond recovery. It thus becomes necessary for the tenant's security, to fix a maximum beyond which the rent shall not rise But if it be necessary, for the tenant's security, to fix a maximum beyond which the rent shall not rise, it is equally necessary, for the landlord's security, to fix a minimum below which it shall not fall. In every transaction of this kind, therefore, there are two points to be determined, a maximum of rent and a minimum, and there is just as much difficulty and chance of error in fixing these two points as extremes as in fixing one point as a medium; or, in other words, as in fixing a certain rent in money"

We have not space to refer at present to the other subjects which the author broaches connected with the lease, but we shall very often have occasion to refer our readers to this work, which is not more distinguished by the sound and impartial views it takes of relations between landlord and tenant, than by the fullness of practical detail into which its experienced author enters, on the several sections of the general management of estates which the former has to superintend.

This work is especially one for the perusal and guidance of landowners and land agents, and we are very sure that amongst such it will be extensively read

Miscellaneous.

Chepstow Farmers' Club.—It is proposed to present Mr. Arthur Hall, Hon. Sec. to the Chepstow Farmers' Club, with a token of gratitude for the important services he has rendered to that Society, and as a mark of the esteem and admiration in which his talents and courteous conduct are held by its members; to which all parties desirous of testifying their approbation are respectfully solicited to subscribe.—Subscriptions will be received by Messrs. Bromage, Snead, and Snead, until the 20th December next.—*Monmouthshire Beacon.*

Mangold Wurzel.—A French newspaper tells the following story of the introduction of this root into cultivation in Flanders. When Napoleon was endeavouring to protect himself against the inconveniences felt from the impossibility of obtaining Colonial produce, in consequence of the activity of the English cruisers, an order was given that measures should be taken to induce the Flemings to grow Beet, for sugar-making The Prefect of the department of Jemappes accordingly invited all the farmers of his district to set about the cultivation of the root, and distributed seed among them. The Flemish farmers hit upon its management immediately, and the first season gave them a large crop. But when the roots were ready nobody knew what to do with them, so the farmers resolved to cart them to the Prefecture. And accordingly, one fine morning, the Prefect was surprised by the arrival of heavy carts, bringing him some hundred thousand kilogrammes of Beet. Having no means of taking it in, for the buildings in which it was to be manufactured had not been thought of, he had no resource but to pay for the crop, and get the country people to cart it away again. This led them to consider whether cattle could not be fed upon it—and the result we all know.

Rolling Wheat.—Rolling Wheat on all soils is universally considered most beneficial, particularly after the frosts have rendered the land frothy. It gives a solidity to the soil, makes the Wheat straw more staple, and has been generally found to render the crop more productive. Carrying out the system of proof adopted in all cases where it can be obtained, the following experiment is corroborated by several trials, and by having one portion unrolled of every field on one farm. It was always performed, not when the land was quite dry, but when it was sufficiently so to work the roll with scrapers. When the soil was quite dry it has not succeeded; perhaps from the want of adhesion of the particles of soil without moisture:—

		£	s.	d.
1838—Rolled		7	2	3
Not rolled		7	0	0
		0	2	3
1838—Rolled		6	2	1
Not rolled		6	1	0
		0	1	1

Besides one hundred weight of straw in addition.—*Bacon's Agriculture of Norfolk*

* C stands for coomb, which in Norfolk means a sack of 4 bushels.

Notices to Correspondents.

Rural Chemistry.—By E. Solly, Esq., F R S, Experimental Chemist to the Horticultural Society of London, Honorary Member of the Royal Agricultural Society, and Lecturer on Chemistry at the Royal Institution, may be had of all booksellers, price 4s. 6d

Benhaft's Patent Hames.—Inon says he finds the price in London is 8l a pair, "but they are not recommended." Particulars can be learnt of Messrs Brace and Box, of Wall sall, Staffordshire.

Dibbling Machine.—*Spectator*—The implement you name is not suited for allotments and such small plots. No implement worked by horses would be suitable there Dr Yelloly's fork is highly praised

Disease in Pigs.—*M B*—There must be something radically wrong either in the locality of the pigstye or the mode of feeding in the former sufficiently warm and comfortable, and free from dampness? If not, correct these matters Do you give your pigs many roots of a watery nature? If so, make an alteration in the diet We can do no more than throw out these suggestions. The disease appears to be hydatids on the liver, &c *W C S*

Fence.—*Constat*—Let the ditch be on the upper side of the hedge—For every ton of hay or straw taken into the yards to cattle, how many tons of dung should come out? and for every 20 tons of roots in addition, how much additional dung? Perhaps our readers will help us. Last year we consumed in yard and house about 1500 tons of roots and 240 tons of straw; and we probably carried out to the field 2400 tons of manure, composed of ⅓ of farm yard dung and ⅔ of earth

How must I Grind Flax seed?—*M F S J*—See "Home Correspondence" of this day.

Irrigation.—*C B*—The best work on the subject, containing practical details, is "The Practical Irrigator and Drainer," by G. Stephens We must, till next week, refer you to it

Moss.—*Icarius*—Try harrowing it in various directions with a heavy many-tined harrow. You may tear out most of it in this way —— Apply 16 to 20 bushels of bone dust to the acre now

Mr Beaun, *of Stone, Aylesbury*, would oblige me much by informing me what he means by a "thin layer of gypsum?" Whether the heap should be more than a foot in height? Whether the gypsum should be strewed on the top of the second layer, as well as the sulphuric acid? Whether, if these two substances be used, there is any advantage in covering the mix over with earth? (the only method I have hitherto used in preventing the escape of ammonia) Whether he removes his manure to the compost immediately from the stalls, or allows it to be trodden about the yard till half decomposed? Whether he means by a single horse cart load, one filled with the raw litter, or with half decomposed? At what he estimates the cost of the gypsum and sulphuric acid, for say ten cart-loads of manure? *B C*

Spring Wheat.—*T H*—We have sown it so late as the first week in April, with good result. It all depends on the season, had we done so this season we should have failed

Thorn Hedge.—*Bathi altidus*—By the word "removal" we understand you to mean the shifting it to another place Cut it down to within a foot of the ground, and remove the plants individually to their new position, which should be dug over for the purpose, and manured with farm yard dung The roots should be injured as little as possible, and they should be taken up with as much earth as will cling to them

Treatment of Milch Cows.—*An Old Farmer*—If you refer to the case of your own cow, we can only say that it is of a singular and peculiar kind, but as this periodical falling appears to be natural to the animal, we cannot suggest a remedy further than advising you to try some experiments with regard to her feeding Food of the most nutritious kind should be given at the period when her milk falls off, or previous to it Try oil cake *W C S*

Winchcombe Farmers' Club.—*J F Pearcy*—Many thanks for your paper and information. We hope that many other Clubs will follow your example

*** At usual, many communications have been received too late.

Markets.

SMITHFIELD, Monday, Dec 2—Per stone of 8 lbs.

Best Scots to Herefords, &c.	4s	0	to	4s	4		
Best Short Horns	3	10		4	0		
Second quality Beasts	3	2		3	8		
Calves	3	4		4	4		
Best Downs & Half breds	4s	0	to	4s	6		
Best Long wools	3	10		4	2		
Ewes and second quality	3	4		3	8		
Pigs	3	8		4	4		

Beasts 4130 Sheep, 27,760; Calves, 108 Pigs, 490

There are a few more Beasts to day, but all are in request at fully last week's prices The very best Scots, &c have in some instances exceeded our quotations and some of the best Short Horns have made 4s 2d The weather being favourable almost everything is readily disposed of There is an small increase in the number of Sheep, but no improvement in the quality The supply Good Sheep are not very plentiful and command a ready sale with prices having an upward tendency The best old Downs more nearly 4s 6d, and a few of the most sizeable Long wools nearly 4s 4d Short woolled sheep in the trade for second rate qualities, but they do not make any alteration in many Veal trade is dull at a small reduction from Friday's quotations nearly everything makes 4s to 4s 6d Pork trade is very heavy

Farmers, Dec 6.

We have a large increase in the supply of Beasts Woollens a few Dutch, and several Irish Heifers several Scots, Runts, and a large quantity of Cows but the best qualities do not appear to be very plentiful for which Monday's prices are maintained, nearly, best Scots, &c. 4s to 4s 4d, best Short Horns 4s 2d to 4s In second rate, however, the proportion being large, we anticipate that of about 2d per stone, a reduction from 4s 6d to 4s 4d The supply of Sheep is rather plentiful for the time of year; trade is not quite so good by 2s per score, few make them 4s to 4s 4d, the latter being an extreme price Lambs 4s 8d to 5s and Lambs, 5s to 5s 8d. The Veal trade is brisk as many as on Monday's quotations, yet not quite so good as last Friday, owing to the sizeable heads of the choicest qualities caused some to be left Pork trade continues very heavy; we cannot quote also Foreign at more than 4s 4d; many very good ones are sold much under

Beasts, 1,080; Sheep, 6300; Calves, 128; Pigs, 270

Per West Smithfield.

HOPS, Friday, Dec. 6

The Hop Market remains in the same state as last week, the demand through Kent has been fair (it is season of the year) to greatest, and fine Hops in pockets are very scarce

Farrington & Shaw, Hop-Factors.

WOOL.—British, Friday, Dec 6

Lincoln holds rather more demand for English Wool since our last, a good deal has changed hands; but we cannot quote any improvement in price, except in some particularly Wools, on some parts of which an advance has been obtained.

James Pusey, Wool Broker.

COVENT GARDEN, Dec. 7.—There has been scarcely any change in the Market during this week. The supplies have been moderately plentiful, and the prices have differed but little. Pine-apples continue to be sufficient for the demand; among them are some fine specimens of Black Jamaica; Queens are rather inferior both in size and quality. Good bunches Grapes are scarce; but foreign sorts are tolerably abundant. Apples of good quality are sufficient for the demand; Pears are also pretty plentiful. Among the latter we noticed good samples of Glout Morceau, Winter Nelis, Beurré Diel, and Passe Colmar. A few fine specimens of Marie Louise have also been in the Market during the week Melons are now over for the season, and Cucumbers are very scarce Oranges are plentiful; Nuts of all kinds are scarcer. Of Vegetables the supplies of most articles are quite sufficient for the demand Cauliflowers are scarce, and Broccoli is not quite so plentiful Savoys, Brussels Sprouts and other Winter Greens are abundant. Carrots and Turnips are also good, and sufficient for the demand. Seakale is small quantities has been brought during the week; it is offered at from 1s. 6d. to 2s. 6d per punnet Small quantities of Asparagus have likewise been offered at from 4s. to 12s. per bundle. Leeks of good quality may be obtained at last week's prices. Radish and other kinds of Salading are generally excellent. Celery, both white and red, is abundant and good. Among Cut Flowers we noticed Cypripedium insigne, Bignonia venusta, Lucuila gratissima, Poinsettia pulcherrima, Cuphea platycentra, Penta-carara, Camellias, Epacrises, Heaths, Helletropes, Cineraias, Amaryllises, Azaleas, Narcissus, Chrysanthemums, Tulips, and Roses.

FRUITS

Pine Apple, per lb	2s to 7s	Oranges, per doz	1s to 1s 6d
Grapes, Hothouse, per lb	2s to 4s	— per 100	8s to 12s
— Spanish, per lb	10d to 1s	— bitter, per 100	12s
— Portugal per lb	1s to 2s	Lemons, per dozen	1s to 2s
Apples, Dessert, per bush	2s to 6s	— per 100	6s to 14s
— Kitchen, 2s 6d to 4s 6d		Almonds, per peck	6s
Pears Dessert, per bushel	2s to 6s	Spanish Nuts, per lb	2s 6d
Quinces, per half sieve	2s to 3s	Cob Nuts, per 100 lbs	10s to 12s
Medlars, per bushel	2s	Nuts, Black sort	2s6
Filberts, per 100 lbs	20s to 24s	— French	12s
Chestnuts, per peck	1s to 2s	— Spanish	2s
Walnuts, per bushel	1s to 2s	— Barcelona	2s
— — shelled	12s to 14s		

VEGETABLES

Cabbages, per dozen	6d to 1s 2d	Garlic, per lb	4d to 6d
Cauliflowers, per doz	2s to 4s	Onions, per bushel	3s to 4s
Broccoli per bundle	6d to 1s	— large per bushel	2s to 2s 6d
Brussels Sprouts, half sieve	1s6d to 2s	— Spanish, per doz	1s 6d to 4s
Scarcel per half sieve	6d to 1s	Shallots, per lb	6d to 8d
— Jerusal, per half sieve	1s to 1s6d	Tomatoes, per half-doz	2s to 3s
Potatoes, per ton	80s to 70s	Capsicums, per 100	4s to 6s
— cwt	2s 6d to 3s	Radishes, per doz	6d to 1s
— bushel	1s6d to 2s 6d	Lettuce, per score	6d to 1s 6d
— Kidney per bush	3s to 4s	Celery, White, per bunch	6d to 1s6d
Turnips, per doz bun	1s 6d to 2s 6d	— Red, per bunch	1s to 2s
Red Beet, per doz	1s 6d to 2s	Endive per score	1s to 1s 6d
Carrots, per doz bun	2s to 3s	Mushrooms, per pottle	10d to 1s 6d
Basil, per bunch	2d to 3d	Small Salads, per punnet	2d to 3d
Seakale, per punnet	1s 6d to 2s 6d	Water cress, per 12 bun	2d to 3d
Asparagus, per bundle	4s to 12s	Parsley, per doz bunches	2s to 3s

MARK LANE, Monday, Dec. 9.

We had a fair supply of Wheat at our Market this morning, which met with a tolerably free sale at our last week's prices, the condition has also improved; there was some inquiry for Foreign Wheat in retail. Canada Flour is dull at from 28s to 29s per barrel A good supply of Barley, which is 1s cheaper for all descriptions White Peas are unaltered in value; Maple and Grey are 1s lower. Beans, both old and new, have declined 1s per quarter Oats are a very dull sale, but prices are fully maintained

Friday, Dec 6

The arrivals of English Wheat have been moderate, and the trade is exceedingly dull at Monday's prices; foreign is inquired after but business is very slow. Fine Barley is rather more in demand, but secondary sorts are very unsaleable. Beans and Peas remain as on Monday. Oats are a dull sale at our late quotations

Double Furze, 25s. per 100. Forms a beautiful flowering hedge.

Double Red Thorn; Double White do.; Single new crimson, 50s. per 100. Sea Pine, from pots, 40s. per 100.

Ribes sanguineum, 12s. 6d. per 100. Kalmia latifolia, 40s. per 100.

Printed Catalogues and Prices of their general stock may be had. Gardeners of experience and ability recommended.

TO GENTLEMEN, NURSERYMEN, SEEDSMEN, AND OTHERS.

MESSRS. PROTHEROE and MORRIS are instructed to Sell by Auction, on the Premises, Windmill Lane, and Camberwell Nurseries, on Monday, December 16th, 1844, and following days, at 11 o'clock, by order of the Sheriff of Surrey, without Reserve, the whole of the choice GREENHOUSE PLANTS, consisting of Fine Double and Single Camellias, well furnished with bloom buds; Erica in fine varieties; Epacris, Azaleas indica, Chorizema cordata, Tropæolum; choice Geraniums, Petunias, Fuchsias, &c.; also the remaining Nursery stock; consisting of choice Pines, Cupressus Juniperus, Vines, &c.: Iris in pots, Evergreen Oaks, Double Blossom Furze, Garrya elliptica; choice Standard and Dwarf Roses; American Plants, including Ghent and other Azaleas; hardy Scarlet Rhododendrons; Magnolias, Kalmias, Hardy Heaths, &c. One and Two-light Boxes, Hand Glasses, Four Tram Carriages complete, Garden Pots, Utensils in Trade, &c.—May be viewed prior to the Sale. Catalogues may be had of Mr. C. T. Holmes, Solicitor, 163, Fenchurch-street; of the principal Seedsmen; and of the Auctioneers, Leytonstone.

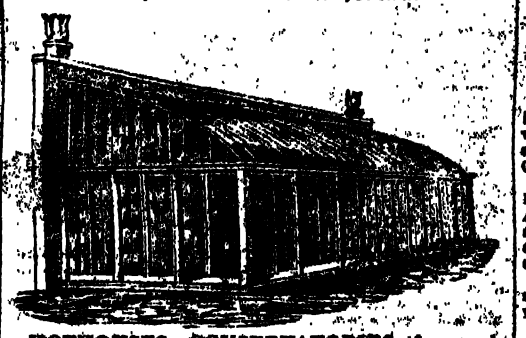
TO MARKET-GARDENERS and Others.—GROVE-STREET, HACKNEY.

MR. WARREN respectfully announces that he will SELL, on TUESDAY, Dec. 10, at Twelve, on the Premises, held by Mr. John Mander (who is quitting them in consequence of their being required by Her Majesty's Commissioners of Woods, Forests, &c., for the Victoria Park), FORTY BOXES and LIGHTS, 200 boxes of healthy Cauliflower plants, seven large beds of red and 20 of early York Cabbage plants; one acre of Red Cabbages, 60 rods of Horseradish; a large quantity of Onion, Cauliflower, White Cors, Colewort, Scalkale, white and red Turnip Radish, long Scarlet Radish, Celery, Curled Endive, and Parsley seeds of the very best quality. Radford's early and Giant Rhubarb, Scalkale, and Asparagus plants, a Waggon and Market Cart, two Horses, Harness, 100 Loads of excellent Spit Dung, Barrows, Ladders, Tools, Watering-pots, and a variety of useful effects.

May be viewed and catalogues obtained, five days prior to the sale, on the premises; of Messrs. BATT and BAILEY, Seedsmen, 412, Strand; Messrs. FLANAGAN and SON, Seedsmen, opposite the Mansion House; at the Rainbow and Unicorn Taverns, Covent-garden, and of the Auctioneer, Isleworth.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very moderate in cost, very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.



D. and E. BAILEY also undertake to repair all descriptions of Horticultural Buildings and Boilers, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient Kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce Lapageria curving near houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. Bailey have prepared a quantity of their Vegetable Plant Protectors, which are now ready for immediate delivery; they beg to intimate to gentlemen, builders, &c. that for Orchidaceous or other Houses, where economy is constantly sought after, the least possible expense in constructing, or of materials required, and which may be seen at their Manufactory.

LIGHT'S IMPROVED BYACINTH POT and SUPPORT, from 1s. 6d. each. Also largest stock in London of Patent and other Garden-pots and Stands, from 15s. to 150s. per dozen, in Wedgewood's and other wares, for Drawing-rooms, &c.—90, Queen's-row, Pimlico.

COTTAM AND HALLEN, ENGINEERS, IRON-FOUNDERS, &c., &c., No. 2, WINSLEY-STREET, OXFORD-STREET, LONDON, and at CORNWALL ROAD, LAMBETH.

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principle, either of iron or of iron and wood combined; which can be fixed complete in any part of the Kingdom, at very low prices.

HOT-WATER APPARATUS for Heating Hothouses, Conservatories, and Greenhouses, Churches, Public or Private Buildings, &c., with COTTAM'S PATENT BOOSTER'S BOILERS. After 15 years' experience, and having made, during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale.

Materials may be had for those who wish to fix their own Apparatus.

THE TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

IRON HURDLES, best Wire for Strained Fencing, Ornamental Iron and Wire-work, Garden Chairs, &c., &c., and every description of Implement for AGRICULTURAL and HORTICULTURAL PURPOSES.

Show Rooms at their Manufactory, 2, Winsley-street, Oxford-street, where a large assortment of the above can be seen.

STEPHENSON AND CO., 61, Gracechurch-street, London, and 17, New Park-street, Southwark, Inventors and Manufacturers of the Improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their much approved method of applying the Tank system to Fineries, Propagating Houses, &c. by which atmospheric heat as well as bottom-heat is secured to any required degree without the aid of pipes or flues. S. & Co. have also to state that at the request of numerous friends they are now making their Boilers of Iron as well as Copper, by which the cost is reduced. These Boilers, which are now so well known, scarcely require description, but to those who have not seen them in operation, prospectuses will be forwarded as well as reference of the highest authority; or they may be seen at most of the Nobility's seats and principal Nurseries throughout the kingdom.

S. & Co. beg to inform the Trade that at their Manufactory in New Park-st., every article required for the construction of Horticultural Buildings, as well as for heating them, may be obtained upon the most advantageous terms.

Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Balconies, Palisading, Field, and Garden Fences, Wire Work, &c. &c.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTONY GIBBS AND SONS, LONDON; WM. J. MYERS AND CO., LIVERPOOL;

And by their Agents,

COTESWORTH, POWELL, AND PRYOR, LONDON; GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.

47, Lime-street, Dec. 7, 1844.

DR. HALLETT'S DRY SOLUBLE FERTILIZERS are, considering their power, the cheapest Manures in use, for they are entirely composed of the Phosphates and other Salts of Ammonia, and other acknowledged powerful fertilisers. They are fairly before the Public as tried things (see No. 33 of the *Gardeners' Chronicle*, &c.). 5 cwt. of either has been found equal to nearly 30 tons of ordinary horse-manure. They are applicable to all sorts of field and garden crops. No. 1 for heavy top growth, as Corn, Hops, &c. No. 2 is for all roots, and a sure preventive of the Fly in Turnips. Price of each, 10*l.* per ton, or 12*s.* per cwt.

DR. HALLETT'S CONCENTRATED LIQUID FERTILIZER is extensively used by Gardeners for improving the size and flavour of fruits and vegetables, and the colours, and perfecting the seed of flowers. Sold in quarts at 1*s.* 6*d.*, and in bottles, six times the size, at 7*s.* 6*d.* Each quart requires 32 gallons of water, to reduce it for use.

Agents for the above. London—Mr. Fothergill, Thames-street; Mr. G. Hallett, the Factory, Broadwall, Blackfriars; Messrs. Warner & Warner, 28, Cornhill; Hurst & M'Mullen, 6, Leadenhall-street; Whittanby, Poultry; Pace & Co., St. Peter's Alley. Norfolk—Bullard and Watts, Norwich. Suffolk—Mr. W. Revens, Yoxford. Leicester—Mott and Co. Gloucestershire—Mr. Batterton, Fairford. Devonshire—Mr. Seward, Plymouth. Wilts—Mr. G. King, Devizes. Glasgow—Mr. D. T. Jackson. Hartlepool, Sunderland, Stockton, and Newcastle—Pace & Co. Dumfries—Green and Co. Further respectable Agents wanted.

CHEAP AND DURABLE ROOFING.

BY HER MAJESTY'S ROYAL LETTERS PATENT

TO GARDENERS, NURSERYMEN, AND OTHERS.

F. M'NEILL & CO., of Lamb's Buildings, Bunhill-row, London, Manufacturers, and only Patentees of IMPROVED PATENT ASPHALTED FELT, for Roofing Houses, Sheds, Verandahs, &c., and for Protecting Plants, and Covering Garden Frames, beg to call the attention of Gardeners and others to their superior article, which has been exhibited at the Great Agricultural Shows of England, Scotland, and Ireland, and obtained the Prize for being the best and cheapest article for roofing, &c. It has been tested in the gardens of several noblemen and gentlemen in the neighbourhood of London, and in different parts of the country, to which reference can be made. The Felt is impervious to rain, water, and frost, and a non-conductor of heat and sound. Its advantages are Lightness, Warmth, Durability, and Economy.—Price ONE PENNY PER SQUARE FOOT.

Samples, with testimonials of its merits, sent free to any part of the town or country.—Patent Felt Works, Lamb's Buildings, Bunhill-row London.

AGRICULTURAL TRAINING SCHOOL, Hoddesdon, Herts, Established for General and Scientific Education, including every branch of Agriculture.

Resident Head Master—Mr. Hazelwood.

Agriculture—Professors Austin, Gough, &c. &c.

Botany—Professor Cooper, F.L.S., Author of "Botany of Sussex," &c.

Chemistry—Professor Holmes, five years Lecturer at St. Edmund's College.

Mineralogy, &c.—Professor Richardson, F.G.S., of the British Museum, Author of "Geology for Beginners," &c.

Management and Diseases of Cattle—Professor Youatt, M.A., Author of "The Horse, Sheep, Cattle," &c. &c.

Practical Surveying and Levelling—Mr. Hazelwood.

The course embraces the Classics, Mathematics, Mechanics, Physics, Chemistry, Botany, Mineralogy, Geology, Land Surveying, Brewing, the French Language, Practical Agriculture, and Lectures on the Breeds, Management, and Diseases of Cattle.

The School Session is divided into two terms, viz., from the 14th January to Midsummer, and from 29th July to Christmas. A library, museum, and laboratory are attached to the school, and the charge for board, lodging, washing, lectures, &c. is so arranged by the committee of management as to include every expense except for books, at Twenty Guineas the half-year.

A Separate Class will be formed of those pupils who are not sufficiently advanced to attend the lectures, the charge for which will be Sixteen Guineas the half-year.

The Introductory Lectures of the several Professors will be public, of which due notice will be given.

Prospectuses in detail are ready, and applications for admission to be addressed to "The Head Master, Agricultural Training School, Hoddesdon, Herts," of whom every information may be obtained.

LIQUID MANURE.

ENGLAND INDEPENDENT OF THE WORLD FOR CORN.

THE Attention of the Agricultural Interest, at this momentous crisis, is requested to the great importance of LIQUID MANURE, and the ease with which it may be appropriated, by the use of FOWLER'S PUMPS, made expressly for the purpose, either portable or fixed; Garden, Ship, and Barge Pumps; also those for Distillers, Brewers, Soap-boilers, and Tanners, for hot and cold liquor. Pumps kept for hire, for Excavations and Wells. Buildings heated by Hot Water, for Horticulture, and every variety of manufacturing purposes.

The Trade supplied on advantageous terms, by BENJAMIN FOWLER, Engineer, &c., 31, Poppet-street, Fleet-street, London.

IMPROVED ROOFING FELT.

M'KIBBIN'S PATENT ROOFING FELT

Is particularly applicable as a Substitute for Slate, Zinc, Tiles, Thatch, and other articles used for Roofing, from its Economy, Durability, and Lightness. It is quite impervious to wet and damp, resists the heat of the sun, and is a non-conductor of heat or cold. Besides the economy in repairs, the timber where it is used may be so light as to save its whole expense. It requires no other coping, and by attention to printed directions may be applied by a common labourer. It is free from breakage and contraction, like zinc, and requires neither painting nor coating. It is now in very general use for Roofing Houses, Verandahs, Sheds, Workshops, Rodewalks, Railway Stations, Icehouses, &c. &c., and for protecting Plants, covering Garden Frames, Cots, and Hay Ricks, the top and sides of Sheep folds; and to Emigrants it provides a cheap, warm, durable, and portable Roof.

This Improved Roofing Felt is much more durable than the common Felt, made in lengths, not being subject, like it or other materials in continuous lengths, to be stripped by storm; and being fastened down at the overlaps only, the wet cannot percolate through the nail-holes.

TESTIMONIAL.

London, Nov. 1, 1844.

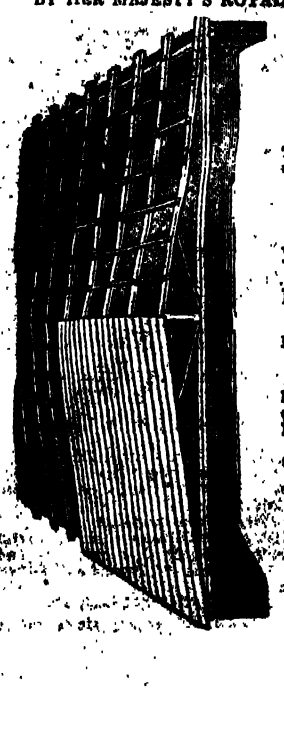
H. C. BOWDEN, Esq., Agent for M'KIBBIN'S Roofing Felt.

It is with much pleasure I add my humble testimony to the superiority of your Felt over any other preparation of the kind with which I am acquainted. This Testimony I give with the greater cheerfulness from the many reports I have heard in its favour, and from the likelihood of its being used extensively in Agricultural purposes. I shall not fail to notice it in my Lectures which on the subject.

(Signed) JOHN ROBINSON, M.B., Senior Lecturer on Chemistry, &c., as applied to Agriculture and Rural Economy in this Kingdom.

Sold in Sheets 32 inches by 20, at 5*d.* each (being less than 9*s.* 6*d.* per square of 100 feet).

Apply to H. C. BOWDEN,



Agent to the Manufacturers,

No. 18, East India Chambers, Leadenhall-street, London.

AGRICULTURAL DRAINING.—THE DERBY LEVEL.—The attention of persons Draining their land is directed to this efficient but simple Instrument, presumed to be all that can be required for the purpose, and its price such as to place it within the reach of all. To be had of the Maker,

J. DAVIS, Optician, Derby.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT ASPHALTE ROOFING, Saving half the Timber usually consumed.

Weight, 24 lbs. per square of 100 feet.

Cost, 8*s.* 4*d.* per square of 100 feet.

The above Material has been used and approved of by the NOBILITY, GENTRY, and AGRICULTURISTS generally, as a ROOFING & COVERING to SIDES of FARM BUILDINGS.

Its advantages are LIGHTNESS, DURABILITY & ECONOMY.

Being a non-conductor, it has been proved an efficient PROTECTIVE MATERIAL TO PLANTS, and is now in use at the ROYAL HORTICULTURAL SOCIETY'S GARDENS, CHISWICK.

It can be had of any length, 32 inches wide, at 1*d.* per foot, super. A discount to the Trade.

THOMAS J. CROGGON & Co., Ingram-court, Fenchurch-st., London.

In 4to, with large Chart, and Steel-plate, Coloured Maps of England, Wales, and Scotland, price 4l. 4s.; or without Maps, 2l. 2s.

CHAPMAN AND HALL'S MONTHLY SERIES.

A COLLECTION of ORIGINAL WORKS of FICTION and BIOGRAPHY.

This Series will be found to differ in some very important respects from every other hitherto presented to the public.

I. It will consist exclusively of new and original works, chiefly of the class of Novels and Romances.

II. The price of each work will be less than one-half the sum charged for an equal amount of matter in the ordinary system of publication.

III. The means by which the saving of cost will be effected will involve no sacrifice of literary or typographical excellence.

IV. The quantity of matter given in each Part will be found to obviate a very general objection made to Serial Works, on the ground of a too frequent suspension of the interest.

The Novel will be published in Four Monthly Parts, of the post octavo form. Each Part will contain 160 handsomely-printed pages, and be sold for Three Shillings. Unless special exceptions are made, and it is expedient to issue a story in a single volume, it is intended that while every Novel in the Series shall contain the ordinary amount at present included in Three Volumes, it shall be completed in Two, and sold for Twelve Shillings.

The Biographies will never exceed Two Parts, or One Volume.

The first Novel will be MOUNT SOREL; or, The Heiress of the De Veres. By the Author of the "TWO OLD MEN'S TALES."

The First Part will be published on the First of January.

London: Chapman and Hall, 186, Strand.

JUST PUBLISHED,

I.

IMAGINATION AND FANCY. By Leigh Hunt.

BLACK ON BREWING—THIRD EDITION.

Just published, Third Edition, 8vo, 10s. 6d. cloth,

A PRACTICAL TREATISE ON BREWING, based on Chemical and Economical Principles; with Formulæ for Public Brewers, and Instructions for Private Families. By William Black. Third Edition, revised and corrected, with considerable additions. The Additions are revised by Professor Graham, of the London University.

"We can recommend this book to such of our readers as practise brewing, either privately or professionally."—*Magazine of Domestic Economy.*

"Invaluable to the practical brewer and private families."—*Chemist.*

"I take occasion, in concluding this article, to refer my readers to the 'Practical Treatise on Brewing,' by Mr. William Black, a gentleman experienced in the business. His little work contains much useful information."—*Dr. Ure's Supplement to his "Dictionary."*

London: Longman, Brown, Green, and Longmans.

SMITHFIELD CATTLE SHOW.—The Widow of the late Thomas Wedlake, Implement Maker, begs to inform her friends her stand at the Show is No. 33, and she solicits a continuance of the favours so long bestowed on her late husband. She will have several useful and well-furnished Agricultural Implements, an inspection of which she respectfully solicits. Please notice the Number, 33.—London Warehouse, No. 116, Fenchurch-street, opposite Mark Lane.

TO LADIES.

ROWLAND'S KALYDOR.—Patronised by the several Sovereigns and Courts of Europe.—An Oriental Botanical Discovery, and perfectly free from all mineral admixture. It exerts the most soothing, gentle, cooling, and purifying action on the skin; and by its agency on the pores and minute secretory vessels, most effectually dissipates all Redness, Tan, Pimples, Blotches, Spots, Freckles, Chilblains, Chaps, and other Cutaneous Visitations. The radiant bloom it imparts to the Cheek, and the delicacy it induces on the Hands, Arms, and Neck, render it indispensable to every toilet. For Ladies, during the period of nursing, and as a wash for Infants, it cannot be too strongly recommended. Gentlemen, after shaving, will find it allay all irritation and tenderness of the Skin, and render it soft, smooth, and pleasant. Price 4s. 6d. and 8s. 6d. per bottle, duty included.

CAUTION.—Beware of Imitations of the most deleterious character, containing mineral astringents utterly ruinous to the complexion, and by their repellent action endangering health. See that the words "ROWLAND'S KALYDOR" are on the Wrapper; and A. ROWLAND & SON, 20, Hatton-Garden, engraved (by authority of the Hon. Commissioners of Stamps,) on the Government Stamp affixed on each bottle. Sold by the Proprietors, and by Chemists and Perfumers.—*** All other Kalydors are FRAUDULENT IMITATIONS!

SLATE WORKS, ISLEWORTH, MIDDLESEX.

THE following Articles, manufactured in Slate for Horticultural purposes, may be seen in use at Worton Cottage, upon application to the gardener (Sundays excepted).

Tank Covers	Bottoms for Frames
Cisterns	Boxes for Balconies and Verandahs
Shelves	
Garden Edging	Orange Tubs, Flower Boxes, &c.

Edward Beck will be happy to answer any inquiries, either personally or by post.

TANNER'S VITREOUS CLOTH, a SUBSTITUTE for GLASS for HORTICULTURAL PURPOSES.—The above recommends itself to the notice of Florists and Horticulturists, as producing effects superior to Glass, at a less expense. The support the Proprietor has received from very many highly respectable Florists encourages him to consider that his labours have not been misapplied in bringing before the public an article so generally required. Price of cloth, 7-8ths of a yard wide, this, 2s. 6d. per yard.; stout, 3s. 1 yard wide, 3s. 6d. Price of Fluid (for renewing the cloth after lengthened service) 1s. 6d. and 2s. 6d. per bottle. Manufactured only by N. W. Tanner, Chemist, Exeter; and Sold by Messrs. Butler and Mawley, Covent-garden, London; Mr. Cunningham, Paradise-street, Liverpool; Messrs. Lucombe and Pince, Exeter Nursery.

PATENT GALVANISED IRON (SORELL'S PROCESS) HOT-WATER PIPES, VAPOUR GUTTER, TANKS, &c.—J. PORTER begs to announce that, in addition to the many other and valuable purposes for which Galvanised Iron is peculiarly applicable, he is now manufacturing Tanks and Gutter for Vaporising, and Pipes for heating by top and bottom heat, Greenhouses, Pineries, Conservatories, &c. J. P. has also to state that, having secured the assistance of parties of the greatest skill and experience, he is prepared to furnish Plans, and Estimates for Heating and Ventilating Horticultural Buildings, Public Edifices, Private Mansions, Churches, Warehouses, Manufactories, &c., accompanied by references to extensive works. J. P. does not profess to offer any one particular system of Boiler as the best to the exclusion of every other, but adapts those which will insure the greatest share of efficacy and economy, in each particular case.—Grove Patent Galvanised Iron Roof and Fence Work, Southwark, second carriage turning to the right from Southwark Bridge.

Printed by William Spanswick, of No. 6, York-place, Stoke Newington, and Frederick Mahony Evans, of No. 7, Church-row, Stoke Newington, both in the county of Middlesex, Printers, at their Office in Lombard-street, in the precinct of Whitefriars, in the City of London; and published by them at the Office, No. 4, Charles-street, in the parish of St. Paul's Covent-Garden, in the said county, where all Advertisements and Communications are to be addressed to the Editor.—Saturday, December 7, 1844.

NOTICE IS HEREBY GIVEN, that in future the MEETINGS of the GARDENERS' BENEVOLENT INSTITUTION will be held at the LONDON COFFEE-HOUSE, Ludgate-hill.—By order, Edw. B. Cutler, Secretary, 97, Farringdon Street.

GARDENERS' BENEVOLENT INSTITUTION.—A GENERAL MEETING of the Subscribers to this Charity will be held at the LONDON COFFEE HOUSE, Ludgate-hill, on the 22d Jan. next, for the purpose of receiving the Accounts of the Institution for the past year, and Electing Officers for the ensuing year; after which an ELECTION will take place from among the following persons, whose Testimonials, &c. have been examined and approved of by the Committee, viz.:—

JOHN BLAYLOCK,	aged	72.	3d Application.
ROBERT CRACKNELL,	,,	72.	2d ,, do.
GEORGE MARTIN	,,	61.	2d ,, do.
JOHN ADAMSON	,,	67.	1st do.
WILLIAM EDWARDS	,,	60.	1st do.
THOMAS FARMER	,,	63.	1st do.
BARNEY FARRELLY	,,	67.	1st do.
JOHN FISHER	,,	69.	1st do.
JOHN GARNELL	,,	77.	1st do.
CHARLES GIBBONS	,,	58.	1st do.
CHARLES GRAY	,,	69.	1st do.
JAMES STEDMAN	,,	75.	1st do.
ANN SUTTLE	,,	67.	1st do.
RICHARD STOYLES	,,	77.	1st do.

No person will be allowed to vote whose Subscription for 1844 is unpaid on the day of Election.

Edward B. Cutler, Secretary, 97, Farringdon-street.

THE ARBORETUM, QUEEN'S ELM, BROMPTON, NEAR LONDON, AND EAST COWES PARK, ISLE OF WIGHT.

RAMSAY BROTHERS, Landscape Gardeners, Contractors for Planting, Earthwork, Road-making, Forming Ornamental Waters, and Improvers in general of Landed Property.

Plans and Estimates submitted, and works contracted for in any part of the Kingdom.

Messrs. R. invite Noblemen and Gentlemen to an inspection of their choice stock of Ornamental Plants, which have been selected from the Arbo of the Parterre and the Shrubbery, and now growing at Queen's-Elm, one mile from Hyde Park Corner.

HEREFORD NURSERIES.

E. P. FRANCIS having received various Testimonials from Gentlemen, &c., as to the excellence and superiority of SNOW'S WINTER WHITE BROCOLI, advertised in the *Chronicle* last season, begs now to inform the Nobility, Gentry, and Public, that it may be obtained at the Hereford Nurseries, Messrs. Noble, 128 Fleet-street, Messrs. Wrench, London-bridge, and Messrs. Flanagan, Mansion House-street, at 2*s*. 6*d*. per oz.

E. P. F. begs further to recommend to those persons who have not yet obtained it, SNOW'S HARDY GREEN FLESH MELON, which was awarded a Knight's Medal at the Chiswick Show in May last, and which cannot be surpassed for hardy habit, most abundant bearer, and delicacy of flavour, over 20 other Melons that were exhibited at the same time. To be obtained at the Hereford Nurseries only, in sealed Packets containing eight seeds, 2*s*. 6*d*. each.

Also, E. P. F. begs to introduce to Public notice SNOW'S HARDY HYBRID BROWN COS LETTUCE, which has been proved by several growers to be superior in favour and sweetness to any other Lettuce grown, very crisp, very hardy, requires no tying up, and is fit for use three weeks earlier than the common Brown Cos, in sealed Packets, 1*s*. 6*d*. each. E. P. F. has also received from Mr. Snow a small quantity of his very fine Chinese Primula Seed, of the white and purple kinds, and all saved from beautiful fringed varieties, in Packets, 2*s*. each.—Dec. 14, 1844.

JOHN BELL begs to inform the Public that he has a large Stock of strong VINES in POTS, two and three years old, from Eyes, at the following prices:—

Strong two-year-old Plants, in pots, 5*s*. each
Ditto three years ditto, 7*s*. 6*d*. each.

Scarlet Hybrid RHODODENDRONS, 6 inches high, in pots, 12*s*. per doz.

Ditto ditto, 12 in., do., 18*s*. per doz.

Also a few hundred fine strong plants of choice SEEDLING CALCEOLARIAS, raised from Magician, Sir Robert Sale, Barnes' King, Miss Ambrobus, Lady Constable, and other first-rate sorts, 12*s*. per dozen plants.—Bracondale Horticultural Establishment, Seed Warehouse 3, Exchange-street, Norwich.

KNAP-HILL NURSERY, NEAR BAGSHOT, SURREY.

HOSEA WATERER (Brother and Successor to the late Michael Waterer), respectfully begs to announce that the American Plants this year are remarkably well furnished with bloom; and with the other articles which are generally required for forcing, he has this season to offer very fine plants of the hardy Scarlet Rhododendrons. This Nursery has long been celebrated as containing the finest Collection of American Plants in the kingdom; independent of this, H. W. is a most extensive grower of Hardy Ornamental Trees and Shrubs, Roses, Forest and Fruit Trees; this may be inferred from the fact, that the Nursery extends over near 100 acres of land. The Knap-Hill Nursery is 2½ miles from the Woking station of the South Western Railway.

All letters intended for this Nursery must be addressed Knap-Hill, near Bagshot, Surrey.— Dec. 14.

TO THE CULTIVATORS OF ROSES.

R. B. BIRCHAM, Hedenham Rosery, Bungay, Suffolk, begs to offer the following Select ROSES, which he can with confidence recommend, as possessing superior quality. A purchaser selecting 12 different kinds from this list, R. B. B. will be happy to supply at 20*s*. The plants are strong and healthy, and varying in height of stem from 1½ feet to 2 feet.

Agnes Sorel	Aurelie Lamare	Las Casas
Donna Sol	Briseis	Idalize
Duchess of Kent	Buffoon	Jambart
Duchesse d'Orleans	Crivelli	Julie
Emperance	Duc de Trevise	La Splendeur
Illustre Beauté	Egle	Nelly
La Ville de Londres	Fleur d'Amour	Becquet
Mrs. Rivers	Gil Blas	Blairii, No. 2
Nicolate	Gurin's Gift	Charles Louis
Petite Renaté	Gurin's Desdanes	De Candolle
Semillasse	Leo the Tenth	Fulgens
Theodora	Lionel Dumourtier	George the Fourth
La Ville de Bruxelles	Madame Dubarry	Eclatante (Moss)
Volumineuse	Reine me Surpasse	Princess Royal
Agathe Dusart	Triomphe de La gueule	Prolifero
Agnodier		Pompour
Antonine d'Ormoise		

Also strong plants of Climbing Roses (Evergreens), at 3*s*. per dozen. These Roses will make shoots upwards of 6 feet long in one season, and are very suitable to cover unsightly fences, walls, stems of trees, &c.

Descriptive Catalogues forwarded upon prepaid application. Plants gratis, to compensate for distant carriage.

Hedenham, Dec. 14.

THE FILBY, or FASTOLFF RASPBERRY.—At the request of some gentlemen living in the neighbourhood of Yarmouth, T. RIVERS begs to submit the history of this really excellent Raspberry to the public. In the year 1814 Colonel Lucas, of Filby, a place lying between Norwich and Yarmouth, discovered a Raspberry plant growing under an old Laurel hedge in his garden. His attention was drawn to it, and he soon found it to be a superior and delicious variety, so that in a short time every other sort was ejected from his garden, and this alone cultivated. It was not, however, till 1824 that he allowed his gardener to part with it, who then gave canes to his neighbours, and by this means it got to be cultivated in Caistor, Ormsby, and, in fact, in all the neighbourhood, under the name of the Filby Raspberry, to the exclusion of all other sorts. It has latterly often been called the Caistor Raspberry, from the Market Gardeners growing it in that parish. In Caistor is an old castle in ruins, that formerly belonged to the Fastolff family: the latter name was given to the variety by Youell and Co., when they first began to sell the canes. The fruit upon which Dr. Lindley pronounced his opinion was gathered in the Filby garden, now the property of the Rev. G. Lucas, who authorises and permits the publication of the above facts; and has also permitted his Gardener to supply the Canes after this date to T. RIVERS only.

Canes are sold at 20*s*. per 100, or 5*s*. per score, carriage paid to London. Charge, for package, for small parcels, 6*d*., for large do., 1*s*. to 2*s*. 6*d*. Orders to any amount can be executed. The Trade price will be given on application.

Sawbridgeworth, Herts, Dec. 14, 1844.

NURSERY LARCH.

COWAN and Co., Nurserymen, Glasgow, have on hand a large quantity of well grown transplanted LARCH, 2 and 3 feet high, which they will sell at a low price, as they must be removed this season. All sorts of Forest-trees, seedling and transplanted, grown extensively, and offered at very moderate prices.

EDWARD BECK informs the Public that in consequence of the greatly increased demand for his SLATE TUBS, he is enabled to reduce the price of the following sizes about 15 per cent. He regrets the too frequent delay which has occurred in the execution of orders. This he hopes to avoid in future by keeping a supply on hand.

Present Prices for Cash or Post-office order:—

14 inches	11*s*. 6*d*.	28 inches	22*s*. 6*d*.
15 inches	12 6	29 inches	24 0
16 inches	16 6	30 inches	28 0
18 inches	20 6		

Slate Works, Isleworth, Middlesex.

WANTED, 1,000 or 2,000 TWO-YEAR OLD SEEDLING HOLLY PLANTS, deliverable in Liverpool. Apply, with price, Box 613, Post-office, Liverpool.

THE TRUE FASTOLFF RASPBERRY.

GREAT YARMOUTH NURSERY. NORFOLK, 1844.

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN, HIS GRACE THE DUKE OF RUTLAND, HIS GRACE THE DUKE OF MARLBOROUGH, THE EARL OF HARRINGTON, THE EARL OF LIVERPOOL, THE LORD BISHOP OF LONDON, LORD VISCOUNT LORTON, LORD SONDES, &c. &c.; as well as by the HORTICULTURAL SOCIETY OF LONDON.

YOUELL AND CO. beg to announce they are able to supply fine canes of the above truly excellent variety, unequalled for the size of its fruit and richness of flavour; prices as follow:—

Packages containing	100	Canes,	£2	0 0
Ditto	50	,,	1	1 0
Ditto	25	,,	0	12 0

For particulars of this above, see Y. & Co.'s Advertisement of Nov. 9th.

YOUELL AND CO. take the present opportunity to state that the above unequalled RASPBERRY is to be obtained only at their Nursery or of their Agents (for the list of whom see their Advertisement of last week); and they recommend their friends to be cautious of whom they purchase, as another Raspberry, under the above title, has been substituted by certain parties as the "true variety." They also publicly deny the truth of Mr. Rivers' statement, "that the fruit upon which Dr. Lindley pronounced his opinion was gathered in what he terms the 'Filby Garden.'"

Also FISH'S EARLY CANTALOUPE HARDY GREEN-FLESHED MELON; for Particulars of which see their Advertisement of last week.

Great Yarmouth Nursery, Dec. 14, 1844.

ROSES, HARDY HERBACEOUS PLANTS, AND HOLLYHOCKS.

WM. JACKSON and Co. beg to offer Collections of the above from their select Stock on the following very reasonable terms:—

100	Dwarf Roses in 50 named sorts; for		20*s*.
100	do. do.	100 do., fine sorts,	35*s*.
100	do. do.	100 do., very fine sorts,	50*s*.
20	Beautiful Scotch Roses, with names,		10*s*.
25	Standard Roses, including the fine Moss and Hybrid Perpetuals,		40*s*.
50	Do.	do. do.	do. 75*s*.
100	Showy Herbaceous Plants		for 25*s*.
100	Do.	100 do., fine sorts,	35*s*.
50	Very fine showy do.	do., in 50 do.,	20*s*., including several new and beautiful species and varieties.

100 Fine named Hollyhocks for 35*s*.

The above are well grown, the Dwarf Roses on their own roots, and from the same stock as those which gave such general satisfaction last season. Plants given to compensate for long carriage. Catalogues will be forwarded on receipt of two postage stamps.

A remittance or reference respectfully solicited from unknown correspondents.—Cross Lanes Nursery, Bedale, Yorks., Dec. 14.

CALCEOLARIAS.

S. STAFFORD, Nurseryman, Seedsman, and Florist, Hyde, near Manchester, begs to observe that his List of Seedling and other CALCEOLARIAS is now ready, and may be had on application. For description of Seedlings see *Gardeners' Chronicle*, July 6th, signed "S. S."; *Gardeners' Gazette*, July 20th and 27th; "Hudson's Cabinet" for September, page 227. Camellias, Fuchsias, and other Greenhouse Plants; Forest and Fruit-trees, Shrubs, &c.; of which Lists may be had.

CORNISH KIDNEY POTATOES.—THE EARLIEST OF ALL EARLY POTATOES. *It is* remarkable that this valuable sort should be so little known and cultivated in England. It is grown to some extent in the West of Cornwall, AND HAS BEEN PRODUCED IN THE OPEN GROUND DURING THE LAST TEN YEARS, FROM 1ST TO 15TH OF APRIL, (on an average.)

Upwards of three hundred acres are annually grown in the neighbourhood of Penzance; and thousands of baskets are sent, by steamers, to supply the London and Bristol Markets.

The growers obtain them so early, that they are enabled to procure an excellent second crop on the same land.

It is a most valuable sort, and should be grown in every garden where early vegetables are required.

Sold in Boxes, at 5*s*., and 7*s*. each, package and carriage free to London or Bristol, which will be forwarded on receiving a Post-office order, on application to WILLIAM E. RENDLE.

Union-road Nursery, Plymouth, December 14th, 1844.

WHITNEY'S PATENT CLOTH for COVERING GREEN-HOUSES, CUCUMBER or MELON PITS, &c. This Cloth is made expressly for the purpose of applying Whitney's Composition upon, and is much more durable than any other material: when coated it is beautifully white and transparent. The perfect success of Whitney's Composition for all Horticultural purposes cannot be more fully established than by stating, that on the 1st of April last, a Black Hamburgh Vine was set in a border, the stem introduced into a house covered with Calico, and coated with Composition. On the 1st of September a bunch of Grapes was cut weighing 16½ ounces; the fruit was finely coloured, and the flavour pronounced to be excellent. A sample was sent up to the Editor of the *Gardeners' Chronicle* for his inspection. The tree grew very luxuriantly, the foliage very fine, and the wood ripened exceedingly well. As a winter protection it is infinitely warmer than glass.

The PATENT CLOTH and COMPOSITION can be obtained of Messrs. Butler & Buckley, Covent Garden Market; Hurst & M'Mullen, Leadenhall Street; Warner & Warner, Cornhill; Barclay & Sons, Farringdon Street; and Hannay & Co., Oxford street. — Wholesale and Shipping Agent, Mr. Bailey, Wolverhampton.

THOMAS JACKSON, of the Priory Farm, Childwall, near Liverpool, begs to inform Nursery, Seedsmen, and others, that he has saved a fine quantity of the Incomparable Hardy Green COLEWORT, which was Advertised in the *Chronicle* of 23d March last. T. J. can refer any person to a respectable Nurseryman in this neighbourhood, as to quality and being genuine. Price 2s. per lb.—Dec. 14.

EXHIBITIONS AT THE GARDEN OF THE Horticultural Society of London,

FOR THE YEAR 1845.

THE DAYS OF EXHIBITION will be the three following Saturdays, viz.: May 24, June 21, July 12.

EXHIBITORS.—All Persons, whether Fellows of the Society or not, will be at liberty to send subjects for exhibition.

FLOWER-STANDS.—Exhibitors of Cut Flowers must SUPPLY THEIR OWN BOXES OR STANDS. No box or stand should exceed eight inches in height at the back, or 18 inches in depth from front to back. The lids of all boxes MUST either be loose or made to unhinge.

MEDALS AND REWARDS.—The Society distributes the following Medals and Rewards,—namely,

	value.— £	s.	d.
C. The Certificate	0	10	0
SB. Silver Banksian Medal	1	0	0
SK. Silver Knightian Do.	1	5	0
LS. Large Silver Do.	1	15	0
SG. Large Silver Gilt Do.	4	0	0
GB. Gold Banksian Do.	7	0	0
GK. Gold Knightian Do.	10	0	0
LG. Large Gold Do.	20	0	0

Exhibitors to whom any of these shall be awarded can exchange them one for another, or may receive their value in money, or in plate. *If within one month after the third Exhibition of the year* no intimation shall have been received from an Exhibitor of the manner in which he desires his Medals to be disposed of, all the Medals due to him may be prepared and *transmitted to him through the usual public conveyances, without further notice.* In case an Exhibitor shall receive a First Prize in any one letter, he shall not be entitled to receive any other Medal in the same letter, except in *K K*, *M M*, and *N N*.

IT IS, HOWEVER, TO BE PARTICULARLY OBSERVED that if any Exhibitor shall obtain the award of a Medal, and it shall be afterwards ascertained that he has gained it by exhibiting plants not *bond fide* his own property, or that of his master, such award shall be cancelled, in favour of the Exhibitor next below him, whose Medal shall in like manner be transferred to the person immediately following him in the award, and so on.

SUBJECTS OF EXHIBITION.—These will be divided into Classes, as explained further on. No articles not of Horticultural produce will be allowed to be placed upon the tables. Exhibitors will do well to make themselves acquainted with the arrangements described in the following List, as they will in ALL CASES BE REQUIRED TO SIGN A PRINTED FORM OF DECLARATION TO BE FURNISHED TO THEM IN THE GARDEN, stating under what letter their plants are to be shown; and they are particularly requested to TAKE NOTICE, that if errors in the awards of the Judges should occur, in consequence of mistakes on the part of Exhibitors in filling up such Declarations, the Society cannot undertake to rectify the errors afterwards.

Names fairly written are to be attached by Exhibitors to all Florists' Flowers; and the Judges are restrained from awarding any Medal to such Exhibitions, whatever their merit may be, if this regulation is not complied with. By Florists' Flowers are meant not only flowers usually so named, but also Fuchsias, Pelargoniums, Roses, and Calceolarias. It is also hoped that all other subjects of Exhibition will be neatly and legibly labelled with their names.

(*Corrected List of Medals, &c.*)

CLASS I.—FLOWERS; for which Nurserymen and Private Growers exhibit independently of each other.

A. Pelargoniums; in collections of 12 new and first-rate varieties, cultivated with superior skill, in pots of 24 to a cast. GB—SG—LS.

B. Pelargoniums; in collections of 12 varieties, in pots of 24 to a cast. GB—SG—LS.

C. Pelargoniums; in collections of six varieties, in pots of 8 to a cast. LS—SK—SB.

D. Roses, in pots; Amateurs to show in collections of 12, Nurserymen in collections of 25, distinct vars. GB—SG—LS.

N.B. It is the wish of the Society, in a future season, to require Roses to be shown exclusively in pots, and not to allow cut specimens to be exhibited at all.

E. Roses in pots; single specimens displaying superior cultivation. SK—SB—C.

F. Moss Roses, in loose bunches, each consisting of three trusses as they are gathered, so as to exhibit, as far as possible, the habit of the variety; in 12 varieties. SK—SB—C.

G. Other Roses, exhibited as in the last letter, and in 50 varieties. LS—SK—SB.

N.B. No one who exhibits in this letter can also compete in the following.

H. Other Roses, exhibited as in the letter F, and in 25 varieties. SK—SB—C.

N.B. Higher Medals than those here offered for Roses cannot be given by the Judges. And if Roses are brought for exhibition without attention to the regulations here explained, they will not be allowed to compete.

I. Cape Heaths; in collections of 20 entirely distinct varieties. GK—SG—LS.

N.B. It is expected that the same plant shall not be exhibited on more than one occasion.

K. Cape Heaths; in collections of 12 entirely distinct varieties. GB—SG—LS.

L. Cape Heaths; in collections of 6 entirely distinct varieties. SG—LS—SK.

N.B. No person will be allowed to show in more than one of the classes *I*, *K*, and *L*.

M. Cape Heaths; single specimens displaying very superior cultivation. LS—SK—SB.

N. Calceolarias, in sizes; in pots of 24 to the cast. LS—SK—SB.

O. Carnations, in pans of 24 distinct varieties. LS—SK—SB.

P. Picotees, in pans of 24 distinct varieties. LS—SK—SB.

Q. Pinks, in pans of 24 distinct varieties. SK—SB.

R. Ranunculuses, excluding Turbans; in stands of 12 distinct varieties for Private Growers, and 24 for Nurserymen. LS—SK—SB.

CLASS II.—FLOWERS; for which all persons are admitted to equal competition.

S. Stove or Greenhouse Plants; in collections of 40 plants. LG—GK—GB.

N.B. Calceolarias, Fuchsias, Orchidaceæ, and Pelargoniums to be excluded from *S*, *T*, *V*, and *W*.

T. Stove or Greenhouse Plants; in collections of 20 plants. GK—GB—SG.

N.B. Exhibitors cannot show in more than one of the classes *S*, *T*, *V*, and *W*.

V. Stove or Greenhouse Plants; in collections of 12 plants. GB—SG—LS.

W. Stove or Greenhouse Plants; in collections of 6 distinct species. SG—LS—SK.

X. Greenhouse Azaleas; in 12 distinct varieties. GB—SG—LS.

Y. Greenhouse Azaleas; in 6 distinct varieties. SG—LS—SK.

N.B. No one can show in both classes of Azaleas.

Z. Stove or Greenhouse Climbers; in collections of 6 species. SG—SK—SB.

AA. Exotic Orchidaceæ; in collections of not fewer than 20 species. LG—GK—GB.

N.B. Exhibitors cannot show in more than one of the classes *AA*, *BB*, and *CC*.

BB. Exotic Orchidaceæ; in collections of 12 species. GK—GB—SG.

CC. Exotic Orchidaceæ; in collections of 6 species. GB—SG—LS.

DD. Scarlet Pelargoniums; in 6 distinct vars. LS—SK—SB.

EE. Pelargoniums; in 6 DISTINCT SPECIES. SG—LS—SK.

N.B. By the word species is meant the wild kinds imported from the Cape of Good Hope, or New Holland, tuberous species inclusive, and not garden crossbreds.

FF. Achimenes; in collections of 6 species, grown in pans not less than a foot in diameter. LS—SK—SB.

GG. Distinct varieties of Tall Cacti in flower. GB—SG—LS.

N.B. The GB and SG Medals are not to be given if fewer than six varieties are exhibited.

HH. Fuchsias; in collections of 12 VERY DISTINCT varieties, of which one-half shall have a light calyx. LS—SK—SB.

II. Cinerarias; in pots, in collections of 12 distinct varieties. SK—SB—C.

KK. New or extremely rare ornamental Plants. SG—LS—SK.

NB. These Medals will be awarded by the Society's Officers, and not by the usual Judges. Exhibitors will particularly observe that none but new or rare plants can be exhibited under this letter. *Nothing will be regarded as new which has been exhibited in the Garden in a previous season.*

LL. Single specimens of very superior cultivation. SG—LS—SK.

MM. Miscellaneous subjects. SK—SB—C.

N.B. Exhibitors under *MM* will not be thereby *entitled* to a pass-ticket. Cockscombs, Heartsease, Hydrangeas, and bouquets are altogether excluded from exhibition.

NN. Seedling Florists' Flowers. SK—SB—C.

N.B. Every seedling must be shown singly, and marked with the name it is to bear. The same seedling cannot gain a prize more than once in the season. Pelargoniums are to be shown in pots, and not in a cut state. No person will be allowed to exhibit more than 6 seedlings at each meeting. Exhibitors under this head will not be thereby *entitled* to a pass-ticket. For seedling Pelargoniums exhibited the first year no higher prize shall be given than a Certificate, and this is to be awarded to flowers of decided merit. Seedling Pelargoniums of the second year must be shown in pots not smaller than 32s, and each exhibitor may produce six of them, but not a larger number.

IN ADDITION to any Medals assigned to the classes *I*, *S*, *T*, and *AA*, the SK, SB, and C are offered for the collections in those classes which shall be best named by the Exhibitor.

N.B. The Society's Officers, who will make this award, will be guided in their judgment by a consideration not only of the correctness of the names, but of the accuracy of the spelling, and the neatness of the writing.

CLASS III.—FRUIT; for which Market Gardeners, Fruiterers, or persons in the habit of regularly supplying the Market, and Private Growers, exhibit independently of each other.

N.B. All Fruit must be FULLY RIPE and WELL-COLOURED and PROPERLY NAMED by the Exhibitor as far as practicable; if the contrary it will be disqualified.

OO. Miscellaneous Collections of Fruit, consisting of at least three different kinds, Peaches and Nectarines being considered as only one kind. GK—GB—LS.

N.B.—Cucumbers, Tomatoes, Gourds, and similar Kitchen Garden produce, are excluded from this letter.

PP. Grapes. SG—LS—SK—SB.

QQ. Pine Apples. SG—LS—SK—SB.

RR. Peaches or Nectarines, in dishes of six specimens. SK—SB.

SS. Other kinds of Fruit. SK—SB—C.

JUDGES.—The Judges have the power of *increasing* or *diminishing* the number and value of the Silver Medals offered by the Society for particular objects, and also of *conferring* Silver Medals or Certificates in cases not contemplated in these regulations, if they think it necessary to do so.

The Judges are also required to bear in mind that the Society's Medals are offered less for new and curious objects than for fine specimens of Horticultural skill, the design of the Council in instituting these meetings being not so much to encourage the Collector as to reward the skilful Gardener. They are also not to make any award in cases where the objects exhibited do not appear worthy of a Medal; otherwise a bad single exhibition might obtain a prize, merely because there is no better exhibition of the same class to oppose it.

By order of the Exhibition Committee, JOHN LINDLEY,
Aug. 31, 1844. Vice Secretary.

*** Copies of these Regulations can be procured upon application at the Society's Office, 21, Regent-street.

In 8vo, boards, with very numerous woodcuts, price 10s. 6d.,

LINDLEY'S ELEMENTS OF BOTANY:

STRUCTURAL, PHYSIOLOGICAL, SYSTEMATICAL, AND MEDICAL.

Being a Fourth Edition of the "Outline of the First Principles of Botany."

Contents of the Work—I. STRUCTURAL and PHYSIOLOGICAL BOTANY:—1, Elementary Organs; 2, Compound Organs; 3, Root; 4, Stem; 5, Leaf-buds; 6, Leaves; 7, Food and Secretions; 8, Flower-buds; 9, Inflorescence; 10, Floral Envelopes; 11, Male Organs; 12, Disk; 13, Female Organs; 14, Ovule; 15, Impregnation; 16, Fruit; 17, Seed; 18, Acrogens, or Flowerless Plants.

II. SYSTEMATICAL BOTANY:—1, Linnæan Sexual System; 2, Analytical Method; 3, Natural System; 4, Natural System of De Candolle (*the Part illustrated with Numerous Figures of the details of the more important Natural Orders*); 5, the Alliances of Plants; 6, Sketch of a New Distribution of the Vegetable Kingdom.

III. MEDICAL BOTANY; consisting of a Classified List of the Principal Medical Plants that are known in a living state in Europe; with an Explanation of the Purposes to which they are applied Medicinally.

TAYLOR and WALTON, and all Booksellers.

ELECTRO-PLATING AND GILDING.—OLD PLATED GOODS RESTORED and made equal to new by Messrs. ELKINGTON and Co.'s Patent Process. This process being carried on in London *only* by *Messrs. Elkington and Co.*, it is particularly requested that all goods may be forwarded direct to their establishments, 22, Regent-street (corner of Jermyn-street); or 45, Moorgate-street, City. New Goods plated upon White Metal in great variety. Books of Prices and Drawings sent to all parts of the Kingdom and abroad free.

PATENT ELECTRO-PLATED AND GILT ARTICLES in every variety, at the Establishments of the Patentees, ELKINGTON AND Co., West End—22, Regent-street, corner of Jermyn-street; City—45, Moorgate-street. The Patent Electro processes being extensively adopted under their licence, the Patentees beg to state that they confine their own Manufacture to goods of a superior and warranted quality only, which invariably bear their mark, "E. and Co.," under a crown. Old articles replated and gilt.

PRINTED FOR

TAYLOR AND WALTON,

BOOKSELLERS AND PUBLISHERS TO UNIVERSITY COLLEGE,

UPPER GOWER-STREET.

DARLEY'S SCIENTIFIC LIBRARY,

FOR THE USE OF

SCHOOLS, PRIVATE STUDENTS, ARTISTS, AND MECHANICS.

IT is the purpose of this Work to furnish a Series of Elementary Treatises on Mathematical Science, adapted to the wants of the public at large. To youth of either sex at public and private schools; to persons whose education has been neglected, or whose attention has not been directed in early life to such studies; and to Artists and Mechanics these little works will be particularly suited. The principles of the various Sciences are rendered as familiar and brought as near to our commonest ideas as possible; the demonstrations of propositions are made plain for the mind and brief for the memory; and the Elements of each Science are reduced not only to their simplest but to their shortest form.

I.

A NEW EDITION (being the fifth) *is now ready*,

A SYSTEM OF POPULAR GEOMETRY;

Containing in a few Lessons so much of the Elements of Euclid as is necessary and sufficient for a right understanding of every Art and Science in its leading truths and great principles.

BY GEORGE DARLEY, A.B.

Price 4s. 6d., cloth.

II.

NEW EDITION (just published),

COMPANION TO THE POPULAR GEOMETRY;

In which the Elements of Abstract Science are familiarised, illustrated, and rendered practically useful to the various purposes of life, with numerous Cuts.

BY GEORGE DARLEY, A.B.

Price 4s. 6d., cloth.

III.

THIRD EDITION,

A SYSTEM OF POPULAR ALGEBRA;

WITH

A Section on PROPORTIONS and PROGRESSIONS.

BY GEORGE DARLEY, A.B.

Price 4s. 6d.

"For students who only seek this limited knowledge of these sciences, there are, perhaps, no treatises which can be read with more advantage than Darley's Popular Geometry and Algebra."—*Library of Useful Knowledge, article "Mechanics."*

IV.

SECOND EDITION,

A SYSTEM OF POPULAR TRIGONOMETRY,

Both Plane and Spherical.

With POPULAR TREATISES on LOGARITHMS, and the Application of Algebra to Geometry.

BY GEORGE DARLEY, A.B.

Price 3s. 6d., cloth.

V.

FAMILIAR ASTRONOMY.

BY GEORGE DARLEY, A.B.

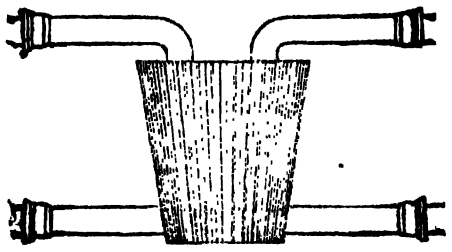
WITH ENGRAVINGS.—12mo, 5s., cloth lettered.

"There is a vast deal of astronomical information conveyed in a most winning and unassuming manner in this delightful little volume, which, not less for the novelty of its plan than the extent of its intelligence, reflects infinite credit on the taste and talents of its projector and editor, Mr. Darley."—*Sun.*

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.



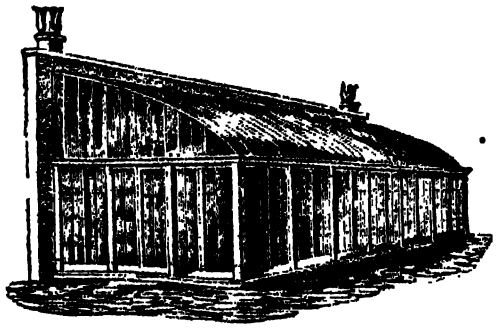
D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

BURBIDGE AND HEALY'S NEW BOILER and FURNACE for HORTICULTURAL PURPOSES.

Registered under 6 & 7 Vict., Cap. 65.

No. 130, FLEET STREET, LONDON.



BURBIDGE and HEALY respectfully inform the Horticultural Public that they have constantly on hand an extensive assortment of their new Boiler and Furnace Doors. In very numerous cases where they have been fixed, they have the highest testimonials of their complete success: for the further assurance of those who may require this apparatus, BURBIDGE and HEALY refer them to the Horticultural Society's Gardens, Chiswick; also to MR. GLENDINNING, Garden Architect, &c. &c., Chiswick Nursery, in the same neighbourhood, where the apparatus may be seen in successful operation, in connection with their new Tanks. The following are the present prices:—

Plain Boiler.			Patent Door and Frames.	Fire-bars & Dead Plate.	Flue Door.	Damper.	Will heat of Pipe.	Forcing Pit, Length by feet.
in.	ft	s.	s.	d.	s. d.	s. d.		
10	1	5	20	7 6	6 2	6	30 feet.	12 to 20
Ribbed Boiler.								
10	2	2	20	10 6	7 6	2 6	50 to 70 ft. 4 in.	Under 25 to 40
12	2	15	30	12 6	7 6	3 6	80 to 125 feet.	40 to 65
14	3	10	35	17 5	8 6	4 6	150 to 250 feet.	65 to 100
18	5	5	42	25 0	8 6	5 6	300 to 400 feet.	Warm a grapery 35ft. long, and a pit 50ft.
24	8	15	50	35 0	8 6	7 6	600 to 800 feet.	

If 3-inch pipe be used, one-third more. If 2-inch pipe, as much more.

The above quantities are rough estimates, which may be varied by enlarging or contracting the fire, or by regulating the fire door. It is possible to heat a much larger quantity of pipe with the boiler, but it would be done at great loss of fuel. The above proportions can be generally relied on as a near approximation to what is correct.

COTTAM AND HALLEN, ENGINEERS, IRON-FOUNDERS, &c., &c., No. 2, WINSLEY-STREET, OXFORD-STREET, LONDON, and at CORNWALL ROAD, LAMBETH.

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principles, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public or Private Buildings, &c., with COTTAM'S PATENT or ROGERS'S BOILERS. After 15 years' experience, and having fixed upwards of 2000 Apparatus for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale.

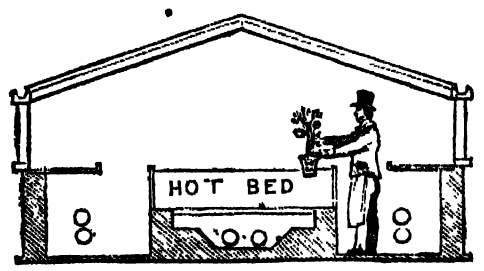
Materials may be had for those who wish to fix their own Apparatus.

THE TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

IRON HURDLES, best Wire for Strained Fencing, Ornamental Iron and Wire-work, Garden Chairs, &c., &c., and every description of Implement for AGRICULTURAL and HORTICULTURAL PURPOSES.

Show Rooms at their Manufactory, 2, Winsley-street, Oxford-street, where a large assortment of the above can be seen.

CONICAL BOILERS.—The Boilers invented by JOHN ROGERS, Esq., are made of several sizes, and may be obtained of JOHN SHEWEN, Ironmonger, Sevenoaks, Kent.



They may be seen in operation at Messrs. Chandler's, Vauxhall; Loddiges', Hackney; Henderson's, Pine-apple-place, Edgware-road; Rollisson's, Tooting; Pontey's, Plymouth; The Horticultural Society's Gardens, Chiswick; and in the Gardens of the Royal Botanical Society, Regent's-park.

STEPHENSON AND CO., 61, Gracechurch-street, London, and 17, New Park-street, Southwark, Inventors and Manufacturers of the Improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their much approved method of applying the Tank system to Pineries, Propagating Houses, &c. by which atmospheric heat as well as bottom-heat is secured to any required degree without the aid of pipes or flues. S. & Co. have also to state that at the request of numerous friends they are now making their Boilers of Iron as well as Copper, by which the cost is reduced. These Boilers, which are now so well known, scarcely require description, but to those who have not seen them in operation, prospectuses will be forwarded as well as reference of the highest authority; or they may be seen at most of the Nobility's seats and principal Nurseries throughout the kingdom.

S. & Co. beg to inform the Trade that at their Manufactory in New Park-st., every article required for the construction of Horticultural Buildings, as well as for heating them, may be obtained upon the most advantageous terms.

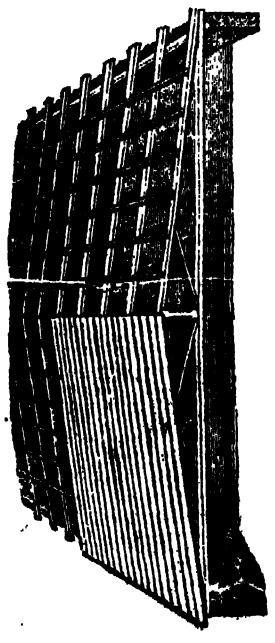
Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Balconies, Palisading, Field, and Garden Fences, Wire Work, &c. &c.

HOT WATER FOR BOTTOM-HEAT.

J. WEEKS AND DAY, ARCHITECTS, &c., Gloucester Place, King's Road, Chelsea, HORTICULTURAL BUILDERS, and Hot-water Apparatus Manufacturers, invite the attention of Horticulturists to their Improved Plan of Bottom-Heat, now becoming so universally adopted.

From the extensive Practice they have been honoured with for 20 years in designing and building CONSERVATORIES, GREENHOUSES, HOTHOUSES, PITS, &c. &c., and erecting their HOT-WATER APPARATUS to every description of Buildings to which heat is applicable, J. WEEKS AND DAY have the greatest confidence in recommending their BOILERS as the most efficient of any yet invented, their largest being capable of heating a range of Forcing Houses 300 feet in length, with a comparatively small quantity of fuel, and only requiring attention once in 10 hours. To be seen in use at most of the London Nurseries, also at their Manufactory; and a variety of Horticultural Erections, Models, Plans, &c. &c.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTONY GIBBS AND SONS, LONDON; WM. J. MYERS AND CO., LIVERPOOL;



And by their Agents,
COTESWORTH, POWELL, AND PRYOR, LONDON;
GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.
47, Lime-street, Dec. 14, 1844.

TO COLONISTS, EMIGRANTS, &c. — Mrs. MARY WEDLAKE, widow of the late THOMAS WEDLAKE, at 118, FENCHURCH-STREET, CITY, informs Emigrants and others that she continues to manufacture those Agricultural Implements for which her late husband was so extensively patronised by the Settlers of South Australia, Van Diemen's Land, Swan River, New Zealand, and other British Colonies. The following articles, made in a very superior manner, are kept on sale at the London Warehouse, viz.:—

Patent Hay-making Machines	Flour-Mills—Bean-Mills
Dressing Machines	Patent Essex Ploughs, 30 sorts
Patent Chaff-cutting Machines	Subsoil Ploughs [Colonies
Oil cake Crushers	Threshing Machines for the
Double action Turnip-cutters	Drills of all kinds—Scarifiers
Railway Wheels	Vacuum Pumps.

Please to be particular in the address, MARY WEDLAKE, 118, Fenchurch-street, London.

BY HER MAJESTY'S ROYAL LETTERS PATENT.

PATENT ASPHALTE ROOFING,

Saving half the Timber usually consumed.
Weight, 24 lbs. per square of 100 feet.
Cost, 8s. 4d. per square of 100 feet.
The above Material has been used and approved of by the NOBILITY, GENTRY, and AGRICULTURISTS generally, as a

ROOFING & COVERING to SIDES of FARM BUILDINGS.

Its advantages are
LIGHTNESS, DURABILITY & ECONOMY.
Being a non-conductor, it has been proved an efficient
PROTECTIVE MATERIAL TO PLANTS,
and is now in use at the ROYAL HORTICULTURAL SOCIETY'S GARDENS, CHISWICK.
It can be had of any length, 22 inches wide, at 1d. per foot, super. A discount to the Trade.
THOMAS J. CROGGON, 8, Ingram-court, Fenchurch-st., London.

IMPROVED ROOFING FELT.

McKIBBIN'S PATENT ROOFING FELT

Is particularly applicable as a Substitute for Slate, Zinc, Tiles, Thatch, and other articles used for Roofing, from its Economy, Durability, and Lightness. It is quite impervious to wet and damp, resists the heat of the sun, and is a non-conductor of heat or cold. Besides the economy in repairs, the timber where it is used may be so light as to save its whole expense. It requires no other coping, and by attention to printed directions may be applied by a common labourer. It is free from breakage and contraction, like zinc, and requires neither painting nor coating. It is now in very general use for Roofing Houses, Verandahs, Sheds, Workshops, Ropewalks, Railway Stations, Icehouses, &c. &c., and for protecting Plants, covering Garden Frames, Corn, and Hay Ricks, the top and sides of Sheep-folds; and to Emigrants it provides a cheap, warm, durable, and portable Roof.

This Improved Roofing Felt is much more durable than the common Felt, made in lengths, not being subject, like it or other materials in continuous lengths, to be stripped by storm; and being fastened down at the overlaps only, the wet cannot percolate through the nail-holes.

TESTIMONIAL.

London, Nov. 1, 1844.

H. C. BOWDEN, Esq., Agent for McKIBBIN'S Roofing Felt.

It is with much pleasure I add my humble testimony to the superiority of your Felt over any other preparation of the kind with which I am acquainted. This Testimony I give with the greater cheerfulness from the many reports I have heard in its favour, and from the likelihood of its being used extensively in Agricultural purposes. I shall not fail to notice it in my Lectures when on the subject.

(Signed) JOHN ROBINSON, M.B., Senior Lecturer on Chemistry, &c., as applied to Agriculture and Rural Economy in this Kingdom.

Sold in Sheets 32 inches by 20, at 5d. each (being less than 9s. 6d. per square of 100 feet).

Apply to H. C. BOWDEN,
Agent to the Manufacturers,
No. 18, East India Chambers, Leadenhall-street, London.

HOT-WATER HEATING APPARATUS.—J. PORTER begs to announce that, in addition to the many other and valuable purposes for which Galvanised Iron is peculiarly applicable, he is now manufacturing Tanks and Gutter for Vaporising, and Pipes for heating by top and bottom-heat, Hothouses, Pineries, Conservatories, &c. J. P. has also to state that, having secured the assistance of parties of the greatest skill and experience, he is prepared to furnish Plans and Estimates for Heating and Ventilating Horticultural Buildings, Public Edifices, Private Houses, Churches, Warehouses, Manufactories, &c., accompanied by references to executed works. J. P. does not profess to offer any one particular form of Boiler as the best, to the exclusion of every other, but adopts those which will ensure the greatest share of efficacy and economy, in each particular case.—Grove Patent Galvanised Iron Roof and Fence Work, Southwark, second carriage turning to the right from Southwark Bridge.

CHEAP AND DURABLE ROOFING.

BY HER MAJESTY'S  ROYAL LETTERS PATENT

TO GARDENERS, NURSERYMEN, AND OTHERS.

F. M'NEILL & CO., of Lamb's Buildings, Bunhill-row, London, Manufacturers, and only Patentees of IMPROVED PATENT ASPHALTED FELT, for Roofing Houses, Sheds, Verandahs, &c., and for Protecting Plants, and Covering Garden Frames, beg to call the attention of Gardeners and others to their superior article, which has been exhibited at the Great Agricultural Shows of England, Scotland, and Ireland, and OBTAINED the PRIZE for being the best and cheapest article for roofing, &c. It has been tested in the gardens of several noblemen and gentlemen in the neighbourhood of London, and in different parts of the country, to whom reference can be made. The Felt is impervious to rain, snow, and frost, and a non-conductor of heat and sound. Its advantages are Lightness, Warmth, Durability, and Economy.—Price ONLY ONE PENNY PER SQUARE FOOT.

Samples, with directions for laying on, and testimonials as to its merits, sent free to any part of the town or country.—Patent Felt Works, Lamb's Building, Bunhill-row London.

REAL SHEFFIELD PLATED DISH COVERS, at prices hitherto unattempted. THOMAS WEST, 18, Ludgate-street, London, having received a large supply direct from the manufactory at Sheffield, offers the best Meat Dish Covers, as follow.—Cottage Pattern—1 Cover of 20 inches, 3l. 19s.; 1 do. of 18 inches, 3l. 3s.; 2 do. of 14 inches, 4l. 8s.; the set of 4, complete, 11l. 10s. ONLY. Double Dome Pattern—1 Cover of 20 inches, 4l. 15s.; 1 do. of 18 inches, 3l. 19s.; 2 do. of 14 inches, 5l. 5s.; the set of 4, complete, 14l. ONLY. In noticing the prices of the above goods, T. W. ventures to assert they are superior to many advertised at a much higher price. Best Wrought Silver Spoons and Forks as usual, Fiddle Pattern, 7s. 2d. per oz. Queen's Pattern, 7s. 4d. per oz. Superior Watches and Fine Gold Jewellery, cheaper than any house in London. West's Hand-book, with 100 Engravings, and full of useful information, is just published, and may be had gratis, and post free, on application to T. WEST, Silversmith, 18, Ludgate-street, London.

BUTTER MADE IN TEN MINUTES.—Much time and labour will be saved by the use of the SUSSEX CHURN, manufactured solely by GREEN and HALE, late Attwood, Wimble, and Warner, Lewes. This Churn being made entirely of block tin, the necessary degree of temperature can be given to the cream by placing the Churn in a pan of hot or cold water, which insures the butter coming in ten or twelve minutes at all seasons of the year. The simplicity of its construction, and the facility with which it may be cleaned, are no inconsiderable advantages over those now in common use.

Sizes	No. 00	0	1	2	3
To Churn	2½lb.	4lb.	7lb.	14lb.	28lb.
Price with pans	16s.	20s.	25s.	32s.	40s.

Delivered (carriage paid) to any part of London.

N.B.—Pans for making clouted cream.

London Agents:—Benham, 19, Wigmore-street, Cavendish-square; Bailey, 71, Gracechurch-street; Yates, Arthur-street East; Deanes, London Bridge. Export Agents, Barnes and Co., 109, Fenchurch-street.

STOOPING of the SHOULDERS and CONTRACTION of the CHEST are entirely prevented, and gently and effectually removed in Youth, and Ladies and Gentlemen, by the occasional use of the PATENT ST. JAMES'S CHEST EXPANDER, which is light, simple, easily employed outwardly or invisibly, without bands beneath the arms, uncomfortable constraint, or impediment to exercise. Sent per post, by Mr. A. BINYON, 40, Tavistock-street, Strand, London, or full particulars on receiving a postage-stamp.

NEW GARDEN SEEDS.

MESSRS. SUTTON AND SONS have the pleasure of intimating to their customers in North Britain and elsewhere, who have annually intrusted them with selecting supplies for the year of home-grown GARDEN SEEDS, that their crops are all now harvested and arranged for delivery, and prices same as last year. The sorts are all the very best in cultivation, and will include all or most of the following

NEW VARIETIES:

Cormack's Prince Albert and British Queen Peas, Sutton's Superb do. (finest known), Shilling's Early Grotto do., Victoria do., Auvergne do., Thompson's Early Dwarf do., True Waicheren Broccoli, Chappel's Early White and Large Cream do., Lake's Superb White do., Howden's Superb Purple do., Hammond's White Cape do., Adey's Large White Cos Lettuce, Ice Cos do., Black seeded Bath Cos do., Sutton's Superb White Celery, Lion's Paw do., True German Cauliflower, Early Dutch Horn Carrot, Long Surrey do., Reading Onion, White Globe do., Lutter's Victory of England Cucumber, Cuthill's Black Spine do., Beechwood Melon, Cabul do., Wonder Longpod Beans, New Dark Windsor do, Early Sixweek Dwarf French ditto, Whyte's New Dark Beet.

Those who have not hitherto honoured Messrs. SUTTON with their commands are hereby informed that the prices of Collections are:—

For Full Collection, being sufficient annual supply for a Large Establishment	£3 0s. 0d.
For ditto, second rate Establishment	2 2 0
For ditto, third rate ditto	1 1 0

The new sorts above-named may be purchased separately, if preferred, at the lowest prices at which such sorts are offered in the Trade. Known correspondents, and such as will give satisfactory references, are not required to remit the money with their orders.

N.B.—Parcels delivered free to any steam-packet or railway office in London, Oxford, or Bristol. Export orders well executed.—Reading Seed Warehouse, Reading, Berks.

TO GENTLEMEN, NURSERYMEN, SEEDSMEN, AND OTHERS.

MESSRS. PROTHEROE and MORRIS are instructed to Sell by Auction, on the Premises, Windmill Lane, and Camberwell Nurseries, on Monday, December 16th, 1844, and following days, at 11 o'clock, by order of the Sheriff of Surrey, without Reserve, the whole of the choice GREENHOUSE PLANTS, consisting of Fine Double and Single Camellias, well furnished with bloom buds; Erica in fine varieties; Epacris, Azalea indica, Chorizema cordata, Tropæolum; choice Geraniums, Petunias, Fuchsias, &c.; also the remaining Nursery stock, consisting of choice Plants, Cupressus Junipervus, Vines, &c.: Ivies in pots, Evergreen Oaks, Double Blossom Furze, Garrya elliptica; choice Standard and Dwarf Roses; American Plants, including Ghent and other Azaleas: hardy Scarlet Rhododendrons; Magnolias, Kalmias, Hardy Heaths, &c. One and Two-light Boxes, Hand Glasses, Four Trave Carriages complete, Garden Pots, Utensils in Trade, &c Also the unexpired term of the Lease of 22 years of the Windmill Lane Nursery, will be sold on Monday, Dec. 16, at 11 o'clock, on the Premises.—May be viewed prior to the Sale. Catalogues may be had of Mr. C. J. Holmes, Solicitor, 163, Fenchurch street; of the principal Seedsmen; and of the Auctioneers, Leytonstone.

TO GARDENERS, FLORISTS, AND NURSERYMEN.

TO BE DISPOSED OF by Private Contract, an OLD ESTABLISHED BUSINESS, in the above Line, with the Dwelling-house, Greenhouses, Land, Buildings, &c., together with a thriving Stock of Plants, Shrubs, Fruit, and Forest-trees of every description. The Nursery Grounds comprise about 10 Acres of Land of the best quality, held on a renewable Lease, with about 12 years to expire, and within a quarter of a mile of a Market-town, having a population of nearly 6000 inhabitants. To an industrious and persevering person the above affords a most advantageous opportunity, the death of the late Proprietor being the sole cause of its being disposed of. Should it not be sold the present owner will have no objection to admit a partner. Further particulars may be known by application to Mr. S. OLIVER, Accountant, Ludlow.

COUNTY OF DORSET.

TO BE LET UPON LEASE, and entered upon at Lady Day, 1845, a FARM upon the Chalk formation, consisting of 1100 acres of Arable, Pasture, Water Meads, and Down-land, with permission to break up the latter. Application to be made to R. S. GRABURN, Esq, Walton in Gordano Bristol.

NURSERY AND SEED BUSINESS.

THE GUILDFORD NURSERY, in full cultivation and work, with one of the first Seed Trades in the county of Surrey, late in the occupation of Mr. THOMAS DICKINSON, deceased, TO BE DISPOSED OF, entire, or a portion of the Land will be taken to by the Landlord.—For particulars apply to Mr. CRAIG, of Addlestone, near Chertsey; Messrs. UKCA and HENDERSON, Strand; Messrs. BATT and Co., Strand; Mr. LEAD, 27, Watling-street; or at the Nursery.

TO NOBLEMEN, GENTLEMEN, TRUSTEES OF LANDED PROPERTY, AND OTHERS.—Messrs. BROOKS and GREEN have an opportunity of introducing a Gentleman who has been accustomed for some years to superintend the Farming department of an extensive Estate, and thoroughly understands the most approved Principles of Agriculture, Breeding and Management of Stock, and who wishes to devote a great portion of his time for the same purpose, in any of the Midland Counties. Satisfactory references will be given as regards capability and integrity, by addressing to Messrs. BROOKS and GREEN, Estate Agents, Surveyors, and Auctioneers, 29, Old Bond-street.

NEW NEWSPAPER.

On Saturday, Jan. 4, 1845, will be published, price Sixpence, stamped (to be continued Weekly), No. 1. of

THE HISTORICAL REGISTER, an Original Journal of Family Events, National and Private Biography, Health, and General News, free from all political bias; under the Sanction and with the Assistance of various Government Departments.

Detailed Prospectuses will be transmitted on application at the Office, 7, Catherine-street, Strand.

ORDER OF ANY NEWSMAN.

WITH 100 PRACTICAL ILLUSTRATIONS.

This day is published, price 15s., handsomely bound in cloth,

THE GARDENER AND PRACTICAL FLORIST, Volume III., containing several hundred Original Papers and Treatises on Floricultural subjects, together with the Garden Practice for the entire Year. A few copies of Vol. I., price 7s. 6d., and Vol. II., price 10s. 6d., may still be had; the Three Volumes comprising the best Miscellany of Gardening ever published.

London: R. GROOMBRIDGE, 5, Paternoster Row.

Price One Shilling.

London:—Published for the Proprietors, at the Office, 194, Strand, where communications, &c., are to be addressed to the Editor.

PROFESSOR JOHNSTON'S WORKS.

I.

LECTURES on AGRICULTURAL CHEMISTRY and GEOLOGY. With an Appendix, containing Suggestions for Experiments in Practical Agriculture. Price 24s.

II.

ELEMENTS of AGRICULTURAL CHEMISTRY and GEOLOGY. The Fourth Edition, greatly enlarged, price 5s.

III.

A CATECHISM of AGRICULTURAL CHEMISTRY and GEOLOGY. Seventh Edition, price 10d.

The Publishers make a deduction when a quantity is taken for Schools, or for Distribution.

WILLIAM BLACKWOOD & SONS, Edinburgh and London.

Recently Published, in 3 large vols. royal 8vo, price 4l. 10s.

THE BOOK of the FARM; Being a Systematic Work on Practical Agriculture, detailing the Labours of the Farmer, Farm-steward, Ploughman, Shepherd, Hedger, Cattleman, Field-worker, and Dairymaid.

By HENRY STEPHENS, F.R.S.E.

Illustrated with Portraits of Animals painted from the Life; and upwards of 600 Woodcuts and Seventy Plates of Agricultural Implements, so particularised as to enable country mechanics to construct them from the descriptions.

"The best practical book I have ever met with."—*Professor Johnson, of Durham.*

"We have thoroughly examined these volumes, but to give a full notice of their varied and valuable contents would occupy a longer space than we can conveniently devote to their discussion; we therefore in general terms commend them to the careful study of every young man who wishes to become a good practical farmer."—*Times*, Dec. 2, 1844.

WM. BLACKWOOD and SONS, Edinburgh, and 22, Pall-mall, London.

THE EDINBURGH REVIEW, No. CLXIII., will be published before Christmas.—ADVERTISEMENTS for insertion are requested to be sent to the Publishers' by Friday, the 20th inst.; and BILLS on or before Saturday, the 21st.

39, Paternoster-row, Dec. 14.

Second Edition, price 1s. 6d.

CHEMISTRY MADE EASY FOR AGRICULTURISTS. By JOHN TOPHAM, M. A.

"A more useful, *practically useful* work than this it would be impossible to place in the hands of a Farmer."—*John Bull*, Sept. 21, 1844.

WHITTAKER and Co., Ave Maria-lane, London.

BLACK ON BREWING—THIRD EDITION.

Just published, Third Edition, 8vo, 10s. 6d. cloth,

A PRACTICAL TREATISE ON BREWING, based on Chemical and Economical Principles: with Formulæ for Public Brewers, and Instructions for Private Families. By WILLIAM BLACK. Third Edition, revised and corrected, with considerable additions. The Additions are revised by Professor GRAHAM, of the London University.

"We can recommend this book to such of our readers as practise brewing, either privately or professionally."—*Magazine of Domestic Economy.*

"Invaluable to the practical brewer and private families."—*Chemist.*

"I take occasion, in concluding this article, to refer my readers to the 'Practical Treatise on Brewing,' by Mr. William Black, a gentleman experienced in the business. His little work contains much useful information."—*Dr. Ure's Supplement to his "Dictionary."*

London: LONGMAN, BROWN, GREEN, AND LONGMANS.

THE HORTICULTURAL MAGAZINE. — Mr. HOULSTON, 154, Strand, will publish, on the 1st of JAN., 1845, Price One Shilling, PART I. of the "HORTICULTURAL MAGAZINE," a New Periodical on Flowers and Gardening.

CONTENTS:—Cultivation of Hardy Lilies—Pruning Forest-trees—Ornamental Timber—Application of Manures—Landscape Gardening—Management of Grape-Vines—Planting Shrubs—Grafting—Hybridising—Horticultural Buildings—Description of New Flowers—Wonders of the Vegetable Kingdom—Designs for Rock Gardens — Irrigating Lands — Select Fuchsias—Hardy Annuals—Reviews—Practical Gardening, and Management of Hothouses, Greenhouses, and Frames—Horticultural Notes, &c.

Advertisements must be sent on or before the 26th of each month.

The Introductory Number, containing a variety of Original Essays, and a Plan of the Work may be still had, price 1s., of THOS. HOULSTON, 154, Strand, London, and all Booksellers.

TALES FROM THE GERMAN. By JOHN OXENFORD and C. A. FEILING. Part the Second, completing the Volume.

Part 23, price 6s.,

MICHELET'S HISTORY of FRANCE. Part the First; to be completed in Four Parts, forming Two Volumes.

CHAPMAN and HALL, 186, Strand.

On the 1st of January will be published, to be continued in Weekly Numbers, price 1½d., and in Monthly Parts, price 7d., stitched in a Wrapper; handsomely printed in large 8vo, double columns, with a clear type, No. 1 of

THE EDINBURGH TALES: Conducted by Mrs. JOHNSTONE, Author of "Clan Albyn," "Elizabeth de Bruce," "Nights of the Round Table," &c. &c.

Under this title will be published a Series of Stories and Novelettes, illustrative of English, Irish, and Scottish Character, Domestic Manners, and Social Duties, by Mrs. JOHNSTONE, and other well-known Writers of Fiction, whose Works have obtained a large share of public approbation.

WILLIAM TAIT, Edinburgh; CHAPMAN & HALL, 186, Strand, London.

CHRISTMAS PRESENT.

With 180 Woodcut Illustrations, price 8s. 6d. in cloth, or in morocco, 14s.,

SYRIA AND THE HOLY LAND; their Scenery and their People, Incidents of Travel popularly described, &c. By WALTER K. KELLY.

"The execution of this work is truly admirable. It reads like an original work, instead of a compilation, being written with spirit, elegance, and an eye for picturesque groupings. The moral, social, physical, political, and geographical features of the East are well brought out, and the reader is at home with the Turk, the Arab, the Jew, the Druse, and the Maronite."—*Westminster Review.*

CHAPMAN and HALL, 186, Strand.

CHRISTMAS PRESENT.

Small octavo, price 7s. cloth, or in morocco, 10s. 6d.

HOURS of MEDITATION and DEVOTIONAL REFLECTION, upon various subjects connected with the Religious, Moral, and Social Duties of Life. By H. ZSCHOKKE. Translated from the German by JAMES D. HAAS.

"It is said, and we believe it to be the fact, that upwards of 200,000 copies of the work have been printed, including the last, which was the twenty-third edition. The volume before us is a selection from the original."—*John Bull.*

CHAPMAN and HALL, 186, Strand.

LIFE ASSURANCE AND ANNUITIES.

THE following are specimens of the low rates of Premium charged by the AUSTRALASIAN COLONIAL AND GENERAL LIFE ASSURANCE AND ANNUITY COMPANY.

Age.....	20	30	40	50	60
Ann. Prem.	£1 10 3	£2 0 7	£2 15 3	£4 1 8	£6 3 9

and of these Premiums one-third may remain unpaid in the hands of the Assured, at interest to be deducted from the sums assured, when they become claims.

Peculiar facilities are afforded for the assurance of the lives of persons proceeding to or residing in Australasia and the East Indies.

Immediate and Deferred Annuities are granted by the Company, on very favourable terms, and it is a peculiar feature in its constitution, that Annuitants participate in the profits.

DIRECTORS.

E. Barnard, Esq., F.R.S.	Gideon Colquhoun, Esq.
Robert Brooks, Esq.	C. E. Mangles, Esq.
Henry Buckle, Esq.	Richard Onslow, Esq.
John Henry Capper, Esq.	William Walker, Esq.

SECRETARY—E. RYLEY, Esq.

For Prospectuses and other Particulars apply at the Offices, No. 126, Bishopsgate Street, corner of Cornhill.

NOTICE is hereby given, that the ACHILLES LIFE ASSURANCE ASSOCIATION has been UNITED with the GREAT BRITAIN MUTUAL LIFE ASSURANCE SOCIETY; and the holders of Policies effected with the said Achilles Life Assurance Association are hereby requested to pay the renewal premiums on such Policies at the Office of the Great Britain Mutual Life Assurance Society, No. 14, Waterloo-place, London. E. GILBERTSON, Secretary.

GREAT BRITAIN MUTUAL LIFE ASSURANCE SOCIETY, 14, WATERLOO PLACE, PALL MALL, LONDON.

The Chisholm, *Chairman.* W. Morley, Esq., *Dep. Chairman.*

GREAT ADVANTAGES OFFERED TO POLICY-HOLDERS BY THIS INSTITUTION.

A large and immediate accession of Assurances, by the transfer of the Policies of the "Achilles British and Foreign Life Assurance Association."

PROFITS.

The whole of the Profits divided ANNUALLY among the Members, after payment of five Annual Premiums.

An ample guaranteed Capital, in addition to the Fund continually accumulating from Premiums *fully sufficient* to afford complete security.

CREDIT.

Credit given to Members for half the amount of the first five Annual Premiums, without security.

Credit allowed to Members for the whole of the first five Annual Premiums, on satisfactory security being given for their payment.

Transfers of Policies effected and registered (without charge) at the Office.

Claims on Policies not subject to be litigated or disputed, except with the sanction, in each case, of a General Meeting of the Members.

Loans granted upon approved Security.

An extremely low Rate of Premium, without participation in the Profits, but with the option, at any time within five years, of paying up the difference between the Reduced Rates and the Mutual Assurance Rates; and thus becoming Members of the Society, and entitled to a full participation in the Profits.

Extract from the Reduced Scale of Rates, for an Assurance of 100*l.*

Full particulars are detailed in the Prospectus.

A. R. IRVINE, Managing Director.

DISEASED AND HEALTHY LIVES ASSURED.

MEDICAL, INVALID AND GENERAL LIFE OFFICE, 25, PALL MALL, LONDON.

SUBSCRIBED CAPITAL £500,000.

THIS Office is provided with very accurately constructed Tables, by which it can ASSURE DISEASED LIVES on Equitable Terms. The EXTRA PREMIUM DISCONTINUED on restoration of the Assured to permanent health. INCREASED ANNUITIES granted on UNSOUND LIVES, the amount varying with the particular disease. Members of CONSUMPTIVE FAMILIES ASSURED at Equitable Rates. HEALTHY LIVES are Assured at LOWER RATES than at most other Offices. POLICIES of twelve months' standing are NOT AFFECTED BY SUICIDE, DUELLING, &c.; and Assigned Policies are valid from the date of the Policy, should death ensue from any of these causes. F. G. P. NEISON, Actuary.

LANDSCAPE GARDENING AND GARDEN ARCHITECTURE.

MR. GLENDINNING, since his residence near the Metropolis, has had the honour to be consulted by a number of Noblemen and Gentlemen in the improvement of their Parks and Gardens, and in the construction and heating of Horticultural Buildings in the most ECONOMICAL as well as effectual manner. He has now made such arrangements as will enable him to devote his particular attention to these important subjects; and Noblemen and Gentlemen desirous of consulting him, are respectfully requested to address him at Chiswick Nursery, near London.

TO THE SEED TRADE.

J. G. WAITE, Wholesale Seedsman, begs to inform the Trade, that his PRICED CATALOGUE is now ready, and can be had on application.

1 and 4, Eyre-street-hill, Hatton Garden, December 14.

The Gardeners' Chronicle.

SATURDAY, DECEMBER 14, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

SATURDAY, Dec. 14	Royal Botanic	4 P.M.
TUESDAY, Dec. 17	Linnean	8 P.M.
WEDNESDAY Dec. 18	Society of Arts	8 P.M.

WHEN, at p. 795, we adverted to the difficulty of obtaining information as to the TEMPERATURE OF SOIL, we had overlooked the very able paper on this subject by Mr. Parkes, Consulting Engineer to the Royal Agricultural Society. If the reader will turn to the volume of that Society's Transactions for 1844, he will see that we are not alone in our regret at finding so little precise evidence upon one of the most interesting and important points to which the cultivator, whether philosophical or merely practical, can turn his attention.

The highly interesting experiments recorded by Mr. Parkes in the paper alluded to, do not touch upon the depth to which frost penetrates the soil, for his observations were made in the summer, and had reference to other questions; but every farmer and gardener in this country ought to learn them by heart. We have, however, been favoured by this gentleman with some unpublished observations bearing directly upon the frost and Potato question, and with his permission we are able to make them public:—

"It may not be uninteresting," writes Mr. Parkes, "to know that I preserved Potatoes in the ground, perfectly, through the excessively hard winter of 1829-30, in France. In that season the Seine carried down ice on the 9th Nov., but it melted again; the ice began to pack up against the various bridges between Paris and Rouen about the 1st Dec., and the river was finally sealed over at Paris on the 9th of Dec. Winter did not break up until the 9th of March, the ice then being from 18 to 20 inches in thickness opposite my house at Puteaux, near Neuilly, four miles from Paris. A long pit, 4 feet deep, was dug in a dry sandy part of the garden, and filled with Potatoes to within 2 feet of the surface, being covered with the same soil quite flat; no straw was used. The bury was opened in the early part of March, and the whole of the Potatoes were discovered to be quite sound; the frost had not even penetrated to the upper layer, and very little sprouting had taken place. During three weeks of this period, I never observed the thermometer hanging in the garden to rise higher than 16½° *below* zero, even during the daytime, with a cloudless sky and brilliant sun. No rain, and but little snow fell during this severe winter, and that little rapidly wasted by evaporation. The hygrometrically dry condition of the atmosphere was evidenced by the rapid drying of linen hung out of doors quite wet; in a minute or two, the clothes were frozen solid, and quickly afterwards they were limber and dry. A large Plane-tree was split open in the same garden during this frost. I discovered, on examining it, that a decayed part of the heart had admitted water, which became a core of ice, about a yard in length, and this burst the tree by its expansion with a loud explosive report—a well-known phenomenon in cold climates, but which I had not before experienced. I also preserved Carrots for the horses, and salads throughout this winter, by lining or walling the inside of a pit, first with stable-dung (a common plan in France), then clean straw against it, and intermixing tolerably dry sand with the vegetables throughout the mass. The Carrots were perfect, and the outer leaves of the Lettuces, Celery, &c. only were affected. No disagreeable flavour was imparted by the dung.

"It may be added, that the severity of this winter was considered by the Parisians to be equal to the *Moscow* winter, 1812. Fires were lighted in the streets for the poor houseless wretches, and many were frozen to death."

These facts testify to the very extreme and long-continued frost that is necessary to bring down the temperature of dry soil to the freezing point at 2 feet deep. In fact, Mr. Parkes's garden was not frozen to that depth during the whole of that rigorous season.

It may be interesting to add, that since the frost of the present year set in, the following has been the actual temperature of the soil in the Garden of the Horticultural Society:—

A Return of the Temperature of the Air and Earth in the Garden of the Horticultural Society.

1844.	Air.			Earth.	
	Min.	Max.	Mean.	One foot deep.	Two feet deep.
Dec. 4	22	40	31	40	43
,, 5	14	35	24½	38	43
,, 6	14	30	22	37	42
,, 7	20	34	27	37	41
,, 8	26	32	29	36	41
,, 9	28	32	30	36	40
,, 10	28	32	30	36	40
,, 11	22	30	26	36	39

From this it appears that in five days after the frost set in this year, the thermometer had fallen within 4° of freezing, at one foot below the surface of the soil; that the cooling down was a slower process than might have been supposed, and not coincident with the air-cold; for it was 3 days after the greatest amount of air-cold was felt before the lowest temperature at a foot below the surface was attained.

Should the coming winter prove a severe one, we trust that some of our friends will make similar observations on this point, or at least ascertain to what depth their soil is frozen. For ourselves, we shall certainly recur to the subject at no very distant period.

Next week we shall resume the experiments on Potato-growing.

WHEN we see a plant which will endure the highest temperature given to stove plants, without being incommoded, and that for many seasons in succession, we naturally conclude that it is not of the class from which SUBJECTS fit for CONSERVATORY CULTURE might be expected. Taking this presumptive evidence, and reasoning, in the absence of direct experiments, we probably exclude many fine plants that would otherwise excite great interest, and give a more exotic cast to our conservatories.

A proof of this may be adduced in the case of Calliandra Houstoni, a plant lately noticed in our Calendar of Operations under the name of Acacia kermesina, for its graceful habit, and fine foliage, and for its flowering in winter. It has been in our stoves for upwards of 50 years, under different names, but was never suspected of being anything else than a stove plant. More recently, however, some one gave it the popular name last quoted, when a place was assigned for it in the conservatory, where, we are told, it has proved to be sufficiently hardy to stand all the year round. In fact in the Camellia-house of Messrs. Pince and Co., of Exeter, it was removed because it threatened to smother the Camellias. Since we are certain that not more than one plant passes under this name, the fact of its being so hardy becomes more generally interesting, for there can scarcely be a more graceful or more suitable plant for covering the bottom of a pilaster in the conservatory—a situation often in want of some such ornament when strong-growing climbers have become naked at the bottom, as they often do after a few years.

In some instances the more hardy stove climbers are now planted out into the conservatory after they have been grown in vineries or other forcing-houses, or in stoves, till they are long enough to reach the top of the house at once, which is kept sufficiently close to afford them the necessary temperature. Many of this class must necessarily be left naked at bottom, where the air of the house is too cold for their young shoots, and thus, a space is left for choice woody plants that are not climbers, among which the subject of these remarks may take a leading place.

At present, when climbers get naked at the bottom, the practice is either to cover the parts with long shoots from the top of the house, or to plant slender-growing climbers round them; but a better way would be to select fine plants, not exceeding ten or twelve feet in a rich border, or that might be easily kept to the required height by pruning; such plants being remarkable for some peculiar feature, such as a graceful mode of growth, fine foliage, conspicuous or sweet-scented flowers, &c. A situation of this kind would suit Luculia gratissima, particularly if it happened to be near the doors or source of ventilation. This beautiful shrub, so lovely at this dull season, although a strong-growing plant, is a delicate feeder, and a strong climber planted behind it may be said to assist its growth rather than impede it, by appropriating to itself the more gross parts of the soil in the border. If the climber, however, is of the very fibrous-rooted kind, like the Ash, few plants can compete with it for nourishment; whereas, such climbers as Ipomœa Horsfalliæ, Combretum purpureum, Beaumontia grandiflora, and most of the Passion-flowers, Hardenbergias, Zichyas, &c., form their roots differently, and are suitable for this kind of furnishing when they become naked below.

Plants for such a purpose ought to be well established, and of considerable size, before they are finally planted out, and all plants, whether climbers or otherwise, that have been first reared in the stove or in heat, ought to be thus treated, otherwise it is found in practice that many of them make little progress for the first season or two. Another cause which operates against the free progress of some climbers is, that for the sake of convenience they are increased from cuttings of the flowering shoots, which are more or less stunted, and the young plants for a time retain that character, until forced by good feeding or strong heat to assume their native freedom; and even after that is effected, if they are afterwards much confined in small pots, they become again stunted; then the best remedy is to cut them down to the surface of the ground, and force them in a hotbed to make a fresh growth. Beaumontia grandiflora, and some of the stove Bignonias, are the first to suffer from either cause; yet when they are young and vigorous they grow from ten to twenty feet in length in one season, and some Bignonias even much more. The former should be about two or three years old, and from 15 to 20 feet in length, before it is planted in the conservatory, where it flowers freely for two or three months, in terminal heads of large, white trumpet-shaped fragrant flowers.—*D. B.*

NATURE AND ART.

IN Nature all plants seem to enjoy a soundness of constitution which bids defiance to disease—no failure of crops or falling off of bloom prematurely; age after age views these inhabitants of mountain and plain luxuriating in wonted vigour, and rarely dying out before a progeny to continue the species has been insured. They may be browsed on by wild beasts, and have their seeds gathered by birds for food; yet they are still found flourishing in their natural habitats, peering forth in humble beauty from the sod, or flaunting with gorgeous festoons in the fitful zephyr. Such are plants, and so would they continue, if left to Nature; but man desires their service and company; their flowers please his eye, and their produce gratifies his palate; and as he cannot at all times afford to travel "from Indus to the Pole," to admire and collect them, he has attempted to domicile his favourites with himself, and with wondrous success. Plants have thus been nursed, fed, petted and fondled, until they have fairly outgrown and excelled the humility of their origin; nor, indeed, would the parent of some of these prodigies be known in its offspring if placed beside it, so little family likeness is there between them. Like spoiled children in general, however, these pets are capricious and delicate, and if returned to their pristine condition, would seldom outlive the change; they have been so habituated to artificial training and luxurious habits, that, thrown on their own resources, they would either pine away or again relapse into savage nature, and become as plain and commonplace as they originally were. Even with all the care and kindness that their guardians can employ, these nurslings frequently get sickly and diseased, falling into consumption, cancer, gangrene, and various incurable maladies, disappointing the hopes of their unfortunate possessors, decimating their ranks, or sweeping them almost entirely away.

Without, however, proceeding farther cacophonically, let us inquire how far Nature and Art seem compatible in the growth of plants, and to what extent we can effect improvements in them for our own purpose, without impairing that constitutional vigour which in their wild state they appear to possess.

The first idea which strikes one on inquiry into this subject, is the latent capabilities of plants in relation to our own wants; and as this principle lies at the foundation of all horticultural improvement, I may, perhaps, be permitted to enlarge a little on the topic. A leading and prominent feature in the mind of man is curiosity, or, as phrenologists term it, wonder. This gives him a desire after, and keen relish for variety, novelty, and change; it is the first faculty which becomes apparent in the restless gaze of the infant, and in the rambles of the child. One new object after another engages its attention incessantly, and handfuls of wild-flowers are successively deserted for the possession of a new assortment. Nature in her extensive domains offers a vast field for the indulgence of this appetite; the mountain and valley, the forest and glade, the sea-shore and inland seclusion, have all been ransacked to furnish objects for its gratification; for the adult acknowledges its sway equally with the tiny collector of roadside beauties. Nature, however, has limits, while the passion for novelty knows no bounds; and thus, at first sight, there seems an incongruity or want of harmony between them; but in reality this is not the case. Plants possess latent capabilities, as I have stated, and man has powers, by the exercise of which these are ascertained and brought out. What are all our florist flowers in Nature, or our fruits without cultivation, compared to the progeny which has been elicited from them! The Tulip might command a passing gaze from the traveller, or the sour Crab-apple a single trial of its unpalatable austerity, but with their occult properties, partially unfolded, the one offers a display, varied and gorgeous in the extreme, to the eye of the beholder; and the other affords a profusion of the most delicious fruit which Pomona can present at her banquet. Thus it is that the vegetable world and man are linked together in the most explicit and intimate union. Plants possess powers of variation and improvement, which in Nature would exist, and continue in abeyance, but for man to call forth and embody them;

and them, on the other hand, has been endowed with propagation, formation, and discharge within such time as to ascertain these dormant capabilities, and work them out to suit his own ends. Must here, it remains, let me remark, that horticulture presents one of the most cogent proofs of a creative Intelligence that natural theology can offer for consideration. Of what use would these hidden powers of plants have been if man, or some such being, had not been present with them, to embody their latent forms? or of what use would have been these adaptations in man merely to operate on plants which doggedly disappointed all his expectations of change? But there is no such discrepancy in creation: the constitutions of man and of plants harmonize with an exactitude so nice, that no species of reasoning can invalidate the inference of their mutual adaptation; and if this is so, it speaks of a creative Power which has planned and completed the beautiful arrangement. He that would sneer, therefore, at the cultivator of plants, knows not his own mental organisation, nor its harmony with the vegetable world; he arraigns the Author of both in a scoff at his neighbour's foible.

Each plant in Nature has its own soil and climate, where the parent, in its old age, will be succeeded by its seedling offspring, and continue thus to thrive as a species without interruption for unlimited years. When we bring a plant under cultivation, we endeavour to place it, as far as possible, under the same circumstances, provided our object be merely its conservation. The nearer we can bring these circumstances to those of Nature, the better will our plant thrive with us; but, in some cases, this is impossible, as when we attempt to cultivate an Alpine plant on grounds near the sea level. The Potato may here be given as an instance; it grows in its wild state on the high lands of Peru, and, of course, under a much lower atmospheric pressure than in any situation in which we are in the habit of cultivating it in Britain. This may be one of the causes of the sickliness of that succulent, now so much complained of; and I imagine that this opinion may, to some extent, be borne out by observation, for the plant is, in general, much less liable to failure in the hilly districts than it is in the low grounds, and on this account seed-Potatoes are generally procured, on account of their vigour, from the former situations. One thing, however, from experience in the cultivation of this root, is clear, that for many years after its introduction, there was no sickliness or death in its ranks—every paring with an eye was sure to sprout forth. The plant must, from the first, have been declining in vigour, although that did not become obvious until frequent mortality gave evidence of the fact: another cause besides—a difference in atmospheric pressure—tended to produce this evil; while the plant was in full vigour with us, we continued to propagate from the same root, not considering that any individual plant must necessarily get old and feeble, and we had not recourse to the only natural process of reproduction by seed, till that feebleness of constitution could only give us a sickly offspring, by which, of course, the evil has not been remedied. We should again have recourse to the plant in its native wilds, import seeds or roots from Peru, renew them occasionally by seedlings from healthy plants, and there will be no danger of losing this valuable succedaneum for bread.* That which gave us a stock of flourishing Potatoes for many years after their first introduction, will, there is little doubt, do so again by a repetition of the same means; if the soil is at fault, chemical analysis can tell us where.

As reproduction by seed is the *only* natural mode of increase with plants, we cannot expect to possess them for any length of time in luxuriance by other modes of increase, however suitable our soil and climate may be for their growth. Of whatever longevity an individual plant may be possessed, old age will at last creep on it with all its feebleness, and although we may protract the period of its natural existence, by transferring a bud or scion to a youthful stock, or give it fresh roots in the soil, it is still a portion of the same individual, and will at last die. Hence it is that many of our fine Pears and Apples are giving way to this imperative law of dissolution, and sinking under their load of years. Here Art fails to preserve for us that which she has reared, and we must go again to Nature for a fresh progeny.

There are several modes by which plants may be varied, or, as I have termed it, by which their latent capabilities may be educed. The mere retarding the growth of Oats, for instance, is said to be sufficient for its transmutation into Rye; and it may be that other annual Grasses and plants may have changes effected in them by a similar process: that subject, however, is yet new, and demands extensive investigation. By excessive nourishment, and repeated sowings of the seeds of plants that bud, we often effect changes of a remarkable nature: many of our finer fruits and florists' flowers have been thus obtained; but the very means employed to effect these changes seem often to impair the vitality of the products, so that it requires constant care, skill, and attention, to preserve the fragile beings in life and health which we have thus given birth to. The fact is that while artificial means seem necessary to effect a change on vegetable forms, Nature is only assiduous in preserving her own, and denies that perpetuity to the results of art, which she vouchsafes to her own uncultivated offspring; so that were the horticulturist to cease from his labours, Nature would again assert her supremacy, and return to that class of forms originally ordained to her trust. In all instances where the highly-bred varieties is had recourse to, in order to effect a change in form or colour, whether in fruits or flowers, this result, stability more or less takes place; and although we remove from the system after obtaining the desired improvement in any plant, still our purpose is not gained; it always retrogrades back and makes approaches to its original type, or continues as liable to disease as heretofore. This evil is often committed where there is no necessity for its occurrence; in the usual routine of nursery business, plants are overstimulated in order to procure an adequate supply of saleable specimens of any new variety, and their future vitality and strength of constitution are thus impaired, so that they often give way under agencies which would not affect them seriously if more considerately treated. How many fine Dahlias, Pansies, and other plants are thus lost, after they, with great trouble, have been procured! From the same excessive competition amongst salesmen, many of our hardy forest-trees are murdered in their infancy. Larches, for example, are reared in nurseries, in a hotbed, comparatively speaking, to their final destination; they are sown thickly in a good soil, suffered to draw each other up to so many saleable inches of growth, reared from any sort of seed that may be conveniently or cheaply come by, without regard to a healthy parentage, and sent out for planting on sterile wastes and bleak slopes of hills, where they are expected to grow and become valuable timber without further trouble. The fact, however, speaks for itself at last, in rotten hearts and unsaleable timber; the soft, spongy heads derived from quick rearing in the nursery, and often perpetuated by close planting and untimely thinning out in the young plantations, decay ere many years, and pumped timber, as it is termed, is the natural result.

By far the most important and extensively applicable mode by which we can vary plants is hybridisation; and here Nature and Art are often compatible in perpetuating fertile varieties which have been in this manner once obtained. It is not at all necessary to enter into the *modus operandi* of this process—every cultivator of plants knows enough of it, and deems it one of the most delightful and interesting of his occupations in the garden. Congeners have been brought from various and far distant climes, and mated with each other in the hothouse and garden, so that their progeny are now, like the Israelites of old, like the very sand on the sea-shore in number. Considering how readily crosses are often effected, it is wonderful how comparatively seldom they appear in nature. There are causes in operation which tend to prevent this. In the first place, plants are more readily fertilised by their own pollen than by that of another; and in the vegetable world there is no superfœtation. In the second place, insects have generally their own particular species of plants, whose flowers they frequent to the exclusion of others. These wild crosses are occasionally, however, evident, as in the Cacti and Aloes, and hence the botanical difficulty of properly defining a species. In crossing, if one desires a healthy sound-constitutioned offspring, the purest plants should be kept as nearly as possible in their natural condition, neither over stimulated nor under-fed, unless it is intended to combine high-feeding and hybridising, which is frequently done, but at the risk of a shorter lived progeny. —*Vidimus.*

* The Peruvian Potato yields much less increase by ... and the stem and seed may, in consequence, ... vitality and vigour. I have grown a Peruvian ... successive years, without a single tuber of ... has merely tripled its size.

ON THE PRESERVATION OF SNOW AS A SUBSTITUTE FOR ICE.

We have no ice-house here: much building has been going forward, and the ice-house was therefore unavoidably delayed till other more important structures should be completed. The following statements with reference to snow as a substitute for ice, will I think show that an ice-house is not essential, nor indeed necessary. Such houses are costly in the first instance, and nothing is more common than disappointments in the preservation of ice.

There is but little water here, and this chiefly running water, which does not very readily freeze. It would have been impossible for us to have filled an ice-house this season or last. The frosts in both years have seldom been of long enough duration, even where water is favourable and in sufficient quantity. Last year I was in hopes of getting some ice, as I had done the former year (about 48 cart-loads; this was preserved till about the beginning of October in a heap on the surface of the ground). Towards the end of January then, last year, we had a heavy fall of snow, and having hitherto had no chance of getting ice, my employer suggested a trial to be made with snow. Accordingly I looked out a place (to be afterwards described), and carted 170 loads in a heap, partly under, and partly above ground, and thatched it over with straw, &c. This stood all the demands upon it, which were considerable, up to February in the present year, when we had another deep snow. The heap was uncovered to be renewed, and it was found there were about 30 cart-loads remaining. To this 196 loads were added. It is deposited in a sort of hole, in a grove of oaks, which, however, do not by any means fully shade it from the sun. The hole is of an oval form, about 50 yards long, by about 18 yards wide at the top, and falls in every way gradually to the centre, which is about 4 feet deep below the level of the surrounding ground. This bottom is a thickly stratified rock, the fissures of which in all probability permit the escape of the dissolving water. In order to make quite sure of this, a drain was cut after the snow was lodged last year. This was easily done, as one side is clear on a rapid declivity. This is the state in which I found the hole; no hoppers, straw, or anything of the kind was left in the bottom. It is difficult to think what such an excavation could have been made for. I conceive the snow to be in the best possible state for collecting and carting when thawing, and quite soft. In this state I commenced with it last year, and this, in the following manner:—All hands proceed to roll snow-balls, and the ground in the direction of the hole being a gentle declivity on smooth Grass in the park, a man can continue to roll a ball till it is above two cart-loads. I have found it prudent to roll a great deal more up to one than I supposed I should need, thereby making ample allowance for a rapid thaw. In the balls it of course keeps much longer. It is compressed by its own weight in rolling. In the soft state described, it is also much easier filled into the carts; and, what is of more consequence, it is in the best state possible for treading in the heap, which it is impossible to overdo. Eight or ten men are stationed at the heap, treading and beating it as brought in. As soon as a sufficient quantity is deposited in the bottom of the hole to render it safe, the horses and carts are driven in at one side over the snow. This is continued to almost the close of the carting. It is so hard, that the horses' feet and cart-wheels make scarcely any impression upon it. They are thus of the most essential service in giving it solidity. It is carried up at first without regard to form, in order to prolong the practicability of driving the horses over it; but eventually it is marked out in a circular form, not unlike the top of a corn-rick, and the sides without such circle thrown on the top, which is about 14 feet above the level of the ground; thus making it 22 feet thick in the centre. It is then covered all over with short Wheat-straw, such as is not fit for thatch, then another covering over this with Fern, found in the Park; finally, a third covering of thatch. These different coverings and thatch are about a yard thick. The hauling this year occupied 6 horses with four carts, and about 17 men, two days; throwing up into form, hauling, and putting on covering, &c., about another half day. This, I feel persuaded, does not exceed the time and cost of filling an ordinary ice-house. I think, too, that the thatch might be dispensed with, which would abridge the labour, and save the most valuable part of the material used. Fern is found near the spot, and this, or short straw alone, of sufficient thickness, I have little or no doubt would answer the purpose. If I am right in this supposition, there is no question with me that the annual expense of collecting and storing ice is, in most cases, much greater than that now described. It will be obvious, that in taking out supplies the heap has by far the advantage; a cart-load may be got in ten minutes. Houses very generally have double and treble doors, and the intervening passages are filled with straw, all which has to be more or less displaced at every time ice is wanted; and when within the house, its atmosphere is unwholesome, and even dangerous, as a correspondent of the *Gardeners' Chronicle* in 1841, p. 797, truly states.

Local circumstances will of course, in some cases, affect the comparative advantages that I have stated snow to possess; as, for instance, where there is a large surface of still water, and the ice-house near to such water, and ice can always be obtained from it, all is well; but were I to have the water, I should be very content without the house. I should then lay in a supply of either ice or snow, just which might come first. Ice, however, has to be pounded small; there is not this labour with snow, and the rolling of the latter takes less time certainly than getting ice off the water, and pounding it; and I think it can more generally and certainly be obtained. Those situated like myself can be in no hesitation. I trust I need not insist that snow answers every purpose quite as well as ice when taken out of the heap, it cannot be distinguished from pounded ice.—*J. W., Salop.*

ACORNS AND THEIR USE.

A PARAGRAPH has appeared in the Papers, giving an account of a great demand for Acorns in Sussex, and great curiosity is expressed at the use that is to be made of them. Without diving into this mystery, the readers of the *Chronicle* will perhaps be satisfied with reflecting that, except when Acorns are very plentiful, which happened to be the case this year, the use that is to be made of them cannot be of any importance to the growers of Oak; plentiful Acorn years are not very common, the severity of our springs often destroying the very early blossoms of the Oak. In general, however, there are Acorns enough to carry on the great purposes of Providence, the continuance of the species of tree which produces the Acorn, and the supply of food for the animals that feed upon them—some useful, others most positively so—though it would be rash to say that any animal in the creation is not useful; among the former may be reckoned sheep, pigs, and deer; squirrels and mice can hardly be defended on the score of utility, as far as we know of their modes of life, though they eat Acorns also.

In all seasons, however, the Oak in general produces Acorns sufficient to carry on one of the great purposes of their creation, as before mentioned—the propagation of this species of tree; and it is of this part of the subject I am going now to treat.

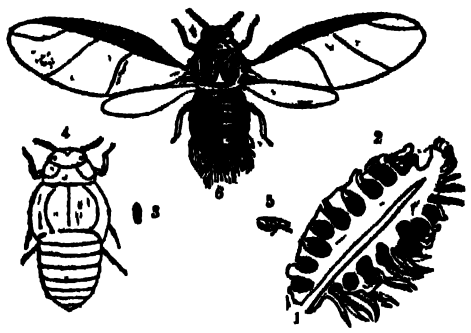
Nobody who has attempted to raise Oak plants in plantations near a rabbit cover, can fail to have observed how soon the plants are attacked by them, and hares are very ready to assist. The observer of any young plantation may also have seen how much sooner a new planted tree is attacked than a young tree grown up from seed naturally sown, or from a stock from a coppice.

to all animals preferred a dry, withered plant to one of a juicy, fresh one, as no doubt they do. Where high wiregrass covered the ground with small branches of timber, particularly the Ash, the observer may notice that Hares and rabbits do not bark their branches till after they have dain a few days, and have become withered and unfit for food.

This circumstance led me to reflect that it would be a more certain way of raising Oak plants—and it is probable the case with seeds of other trees—if the ground intended to be planted were to be prepared and sown with Acorns, instead of planting the trees accordingly, almost ten years ago, I prepared a few acres of land, in the immediate neighbourhood of a fox-cover full of rabbits, which harassed, in spite of their enemies, the foxes, and sowed it with Acorns, without any fence whatever to keep off the rabbits. The Acorns were sown in drills, far apart, with a view to clean the ground from weeds as the Oak plants came up, and also for the facility of transplanting the Oaks, if required. The Oaks came up in plenty, but not very regularly, some not appearing for nearly two years; which was all against the experiment, and evidently occasioned by some of the Acorns having been sown too deep—a great error in seed-sowing: however, with this disadvantage, the seedlings fairly beat the rabbits, and even afforded protection to a colony of hares, that took refuge in the cover of the young Oaks. Besides the casualties among the seedlings, above 500 were annually transplanted as single trees into vacancies in an old wood; and, in spite of hares and rabbits, many succeeded, though outstripped in size and height by those left in the seed-bed. This plantation was examined this year, and the result was as above described, many of the trees varying from the height of 10 to 12 feet.

The plantation was regularly thinned out a few years ago, and before long will require another thinning; part of it had been cultivated, and on that part the trees grow least well. As to the time of sowing the Acorns, I should recommend following Nature, that is, sowing the Acorns when they drop ripe from the tree; they then soon vegetate, after which mice will not touch them, for they appear most fond of them when dry; pheasants are then, also, apt to scratch them up, for Acorns have many enemies to contend with, even before they grow into trees, but will beat them all, if man gives them fair play afterwards, in thinning, and judicious, moderate pruning. —*M. D. P.*

ENTOMOLOGY.



THE SPRUCE-CONE GALL APHIS.—(*Sacchiphantes Abietis.*)—The economy of an insect, probably nearly related to the present one, was discussed in my last Essay, and I shall now give a detailed account of the animals which cause the curious pseudo-cones, so much resembling the genuine fruit of the Spruce, upon which they are formed, that even naturalists have been deceived, and mistaken them for a modification of the cones.

In the third vol. of this Paper, p. 630, will be found a good figure of a sprig of the Spruce Fir, exhibiting these galls, and one which I divided longitudinally showed the structure represented at fig. 1, exposing eight cells on one side and nine on the other; but there were probably 50 cells altogether, as they were packed all round the circumference in about 12 rows; the woody stalk passed through the centre unaffected, but the bark was greatly thickened by the secretions injected by the female insect when the eggs were deposited, and forming oval cells exceedingly

smooth inside, and opening with a transverse suture or mouth, which is closed until the embryo brood has been fed, perfected, and changed to their pupa state; the upper lip projects, the under one is lobed in the centre, and supported by the leaf, which is very short, and forced back as this lip recedes from the upper one, to allow the insects to issue forth.

In the beginning of last August some of the Spruce Fir galls were sent to me from Lanark, which produced winged and wingless specimens in multitudes, the latter being the pupæ. The galls were produced towards the tops of the twigs, but there were younger and smaller excrescences formed above them, which were solid when cut through, and these, of course, kept up a succession of broods. Towards the end of the same month I found two spikes of the galls on a Spruce Fir; they were beautifully formed, of a charming green colour, and looked like Pine-apples in miniature: on pulling off the scales I found the flesh-coloured larvæ powdered over; they were similar to the pupæ (fig. 4), and it is I think clear that these were the offspring of eggs deposited early in the year; they were imbedded as usual in somewhat imperfectly-formed cells (fig. 2), the partitions appearing like a reticulous membrane. The pupæ are of a lead colour, being covered with a kind of powder or bloom; the head is broad and rounded, with a small black eye on each side, and a very minute black ocellus on each side of the antennæ; the prothorax is not much broader than the head, and the alitrunk is the broadest part of the animal; the sides are convex, margined, and slightly green, from the incipient wings shining through; the antennæ and legs are short and coherent: the former are filiform and five-jointed, the latter are tapering and simple. When these Pupæ are sufficiently developed, they fix themselves by their feet and crawl out of their skins, which are of a yellowish-white colour, and remain sticking to the leaves, as soon as they have cast off their coats, they become considerably shorter and of a greenish colour; the crumpled and contracted wings are spread out like little bright green pinions. One of the pupæ which I saw preparing to change, having attached itself, waved about a little for some time to contract itself and determine all the fluids to its thorax. I then perceived a small white margin to the tail, which was the loose skin that shortly formed a wrinkle down the back; this was followed by a crack along the thorax, which, widening, soon extended to the head, and became by degrees sufficiently enlarged to allow the head to emerge, sliding out so gradually that it was scarcely possible to detect any motion; yet shortly after, the first pair of legs was liberated and hung down, and so of the other two pairs successively; but they were not used, as I expected, to assist it in crawling out; and when the tail alone remained enveloped in the skin, the animal raised and depressed itself alternately, with unusual force, employing its legs a little, whilst the antennæ were set at liberty and vibrating; and this seemed to be the most difficult part of the operation, for I observed two of them walking about with the exuviæ still adhering to their tails. Immediately after its birth it appeared very weak on its legs, but soon walked off to a vertical position, where it remained nearly quiet, the wings expanding and becoming paler, until in twenty minutes they were completely developed, and I think that the entire change did not occupy more than forty minutes.

The perfect insect (fig. 5, natural size; 6, magnified and flying), is of a dull yellowish or ochreous green; the eyes are black, remote, and granulated, and close to each on the crown is a bright ocellus; the antennæ and legs are transparent green, the former are short and five-jointed, the latter have biarticulate tarsi and very minute claws; the rostrum is somewhat short and rests between the anterior coxæ; the wings are greenish-white, the superior having a portion of the costa very bright green; the costal nervure the strongest, the others are very indistinct; the first forms an oval apical cell, the second is oblique, as well as the third, but this is curved at its origin. The head and thorax become blackish as they get older and rubbed, and the wings after death fade to a pale browniah tint, and the costal nervures become rosy. Most of those which hatched under my glass bell were males, but a few had more acuminated tails, and these, I suspected, might be females, but I had no further evidence.

As there are excellent characters for distinguishing this group from Eriosoma, especially in the neuration of the wings, which are strikingly different, I shall propose the generic term of *Sacchiphantes*, or sack makers, for them, and I think it exceedingly probable that the Larch species will associate with this group. Linnæus named our insect Chermes Pini Abietis, and De Geer described it as the Aphis gallarum Abietis.—*Ruricola.*

ROSE GARDEN.—No. XXII.

(*Continued from page* 812.)

THE following brief List may perhaps prove acceptable to those who desire to collect some of the varieties most desirable to possess; no attempt has been made, however, to classify them, with the exception of defining in a *slight* degree the purposes for which they are most adapted.

CLIMBERS OR STANDARDS.

Lamarque.—Flower large and brilliant white, always expands well, and every bud formed comes to maturity; very fragrant, very free in the flower, which keeps and blows well in water when cut; the foliage is good, the growth rapid, but it requires much sun and some management in pruning; is rather delicate in some soils and aspects, but is the most perfect of all Roses for beauty, fragrance, colour, and freedom of flowering combined, where it does succeed; and it flowers twice, remaining each time long in beauty, the flowers being frequently much above 12 inches in circumference.

Madame Desprez.—A most hardy climber, fragrant; free in flower, fine in foliage, vigorous in growth; it stands at the head of the red climbers, as Lamarque of whites, but although the flowers are neither so fragrant nor so well expanded as the Lamarque, the wood is more hardy and foliage more rich.

Fortune Desprez.—Colour of the flower flesh-yellow; habit like Lamarque, and like it, somewhat tender in winter or rather in the spring, at the rise of the sap; not so fine however in the flower, and the petals fall off when this flower is cut for bouquets; its chief value lying in its singularity.

Rupa.—Rapid in growth, free in flower, fragrant in smell, the best adapted for arbours and lattice-work, and may be trained and cut with perfect facility.

Brennus odorata alba.—Desirable to cover a wall as an evergreen; but the flower does not expand: this Rose differs from the Maria Léonidas, in being more vigorous and yielding buds with perfect eyes more freely; its growth is rapid, its branches tortuous, appearance wild.

Princesse Nassau, Princesse Helene, Félicité Perpetuelle.—For wild growths, to stand singly, &c., some of which train well.

Brennus.—Colour splendid, size large, shape perfect, scent very fine, vigorous in growth, requires much wood to be left in pruning, very healthy, and perhaps the handsomest Rose of that character known.

Fulgens.—Colour brilliant, growth strong, moves well, but grows so fast it should not be left long in one place, if to be transplanted.

Félicité Perpetuelle.—Profuse in flower, healthy, vigorous, fast in growth, and hardy.

Lilac Noisette.—Very free, and continually in flower.

Bougainville Noisette.—Flower free, but small; not so vigorous as many others.

Common Noisette.—Seen everywhere; but the colour is clear, and habit of growth desirable.

Bouton Nankin.—Buds nankeen coloured; singular in appearance.

Bilhard, Conque de Venus, Blairii, Bourcault Amadis, Dr. Roake, Perpetuelle de Newby, Belle Elvire, Princesse Helene, Princesse Nassau, Ariel.—Colour intensely bright, wood healthy, growth free.

STANDARDS AND DWARFS.

Brennus, Mordaunt de Launay, Aimée Vibert, Conque de Venus,—Flower in bunches freely, colour delicate, growth free.

Queen of Bourbons, Queen of Belgians.—Beautiful colour.

Archduke Charles.—Colour dark and uncommon, foliage particularly rich, leaf large.

Napoleon Bourbon.—Continues late in flower.

Attelaine de Bourbon.—Colour bright, and flowers produced twice.

L'isle de Bourbon.—Colour bright; flowers once only.

Bourbon Nankin, Dr. Bilhard, Noisette Bougainville.—Free in flower, colour rosy lilac.

Noisette Fellenberg.—Colour bright, growth free.

Belle Auguste, Vivaricus, Charles Auguste, Madame Hardy.—Vigorous in growth, colour brilliant white.

Enchantress.—Formal in shape, very double, no scent, healthy grower.

Josephine Antoinette.—Formal in growth, perpetual, scent fine.

Bourbon Faustine, Noisette Paeoniflora, Ariel, Autumnus Perpetual, Madame Lafay, Père Bernard, La Biche, Euphrosyne, Noisette de Luxemburg.

Smith's Yellow Noisette.—Splendid yellow, opens badly; when cut for nosegays the buds should be opened with the fingers or the breath; scent fine.—*A. H. B.*

NOTES ON AMERICAN PLANTS.

[FROM PERSONAL OBSERVATION.]

(*Continued from page* 276).

Gerardia quercifolia.—I was much pleased when, for the first time, I saw this noble species in flower, and imagined that I had discovered a new plant; but on consulting my American Flora I was soon undeceived. Of all the herbaceous plants with which I am acquainted, there are few, if any, that surpass this in beauty. It grows about three feet high, branching out about 18 inches or two feet horizontally all up the stem, and loaded with flowers as large as those of a Gloxinia, and of nearly the same shape, the colour being of a brilliant yellow. This beautiful plant, although not grown in England, is common in many places in the States. I found strong plants growing in light sandy loam, and near the edges of woods, exactly in such places as we often find the common Foxglove growing with us. Some of your readers having correspondents in America, might easily procure seeds or roots, and try their skill in flowering it: if they succeed they will not begrudge the trouble.

Gerardia flava.—This may be called the yellow Foxglove of America—a most beautiful plant. The flowers in size and colour are nearly the same as the preceding, but growing with a single stem about three feet high, with a densely covered spike of bright-yellow flowers as large as the common Foxglove. It grows in situations similar to G. quercifolia. The best time to procure plants would be in the month of June, before they begin to throw up their flower-stems, and plenty of seed may be obtained in the autumn, as they seed freely. I am surprised that these two beautiful plants are not as yet found in our collections, and should be glad to hear of some one being successful in their cultivation. I also met with two or three annual species, which were very handsome, with finely-divided foliage and small purple flowers, exactly resembling Boronia pinnata, when viewed at a little distance; they would make beautiful pot-plants for autumn sowing.

Liatris.—This is a beautiful genus, containing species well worthy the attention of all plant-growers. The spikes are of various forms and heights, some of the kinds are nearly as graceful as Humea elegans, and all produce the most inimitable brilliant purple flowers; nothing can be more beautiful; their bulbous roots are

frequently imported to this country, but I have never seen or heard of their being successfully cultivated. They are all natives of the Southern States, and their time of flowering is October and November. Now, it appears to me that if they were grown in pots on the one-shift system, with two or three bulbs in each pot, and treated like hardy greenhouse plants, or like Chrysanthemums, they would succeed well; they would come into flower at the same time as Chrysanthemums, and form a fine contrast with them. It is of no use to treat them as hardy plants (as I have seen done), as, even after the long hot summers of the Southern States, they do not flower till October; the *bulbs* are in fine order for taking up just when the plant is in full flower, so that autumn is the time to give orders for them; and I have no doubt, if well managed, they will make a valuable addition to our winter flowers.

Asclepias tuberosa.—This beautiful plant is well worth general cultivation; it grows in dry sandy and rocky soil, rooting deep into the ground; it should be planted in a warm sunny aspect, and should never be disturbed afterwards. When I lived in Devonshire, I had a plant of it growing in sandy peat, which a few years after planting produced annually from 40 to 50 flower stems, terminating in heads of the most dazzling scarlet; it continued a long time in flower.

Asclepias quadrifolia.—This is the next best of the genus that I met with; I found it invariably growing in shady woods. The flowers grow in heads about the size of Hoya carnosa; they are of a delicate white colour, and the plant is altogether of a most graceful habit, and well deserving a place in any collection.

Lilium superbum, canadense, and philadelphicum, are all very beautiful plants, and well worthy of a place in every garden. L. superbum grows in most meadows, where I found it of the height of six feet, with 50 or 60 fully expanded flowers on a single stem. L. canadense delights in open, dry situations; it is more highly coloured than the last; it grows from 2 to 3 feet in height. L. philadelphicum I invariably found growing in dry shady woods, not in masses like the two former species, but in solitary stems, thinly scattered here and there through the woods; it is the most brilliant in colour of all the American Lilies, and grows from 1 to 3 feet high. To cultivators of exotic Liliums the above are well deserving attention, and I make no doubt but that they would succeed well in this country. I would recommend them not to be disturbed for years after they are planted, and I always found the bulbs from 12 to 18 inches deep in the ground.

Houstonia cærulea.—I met with nearly half an acre of this in full flower on the banks of the Schuylkill River, growing on a poor sandy soil. The sight was so beautiful that I shall never forget it; I notice it here because I am fully persuaded that it would make a most excellent greenhouse annual; it seems too delicate to be treated as a perennial. Abundance of seed might easily be procured.

Convallaria racemosa.—This may be called the American Queen of the Meadows; it is very showy, and grows in damp situations like Spiræa ulmaria, but in larger masses. I once noticed a large mass of it in the middle of a Grass field; it had a very fine appearance contrasted with the dark-green Grass surrounding it.

Cnicus odoratus.—This is a delightfully fragrant dwarf Thistle, growing about a foot high, with large purple flowers; it is well worth growing on account of its sweetness, and I should think would be an excellent bee flower; if I rightly remember it is a biennial.—*H. Read, Noble Thorp.*

THE ANTIQUITIES OF GARDENING.

No. II.—Extracts from Sir Thomas Hanmer's Manuscript on Gardening.—1660, 1670. *(Continued.)*

"*Tulips.* I have found by experience that the best Tulips do not prosper in a great spatious garden, where cold winds have power on them, nor in borders among bushes or other shading plants, but thrive best by themselves, in some warm well-sheltered ground from the spring easterly winds; yet they delight in a sweet air, and not to be too closely pent up.

"It is impossible to say which are absolutely the best Tulips, there being such variety of most beautiful ones of several colours, well sorted together; some with great bold panaches or stripings, others with weaker smaller marks; some of deep colours, others of pale only; and some with white, others without. Amongst the most knowing florists, some fancy one sort, some another, yet they ever agree in these things, so necessary to make up a good Tulip,—that the flower bee of a good form, that is, neither too great and flapping, nor too small and starved; that it open well, and therefore the figure must not be very raised, neither must the petals be too sharp-pointed; that the stamyns be large and of a purple colour, not greenish nor yellow; that the white be a clean pure white, from the first opening of the flower, and not turn white from yellow at the first, as many do that are esteemed reasonable good flowers; that the other colours be thick and rich, shewing like an enamel, distinct from each other, and not confounded; that the blew bottom bee spent away in all or most of the petals; and lastly, that the stalk be not weake, which makes the flower to hang down the head, but strong and of a competent length. These are the chief qualities of Tulips which now come to my mind.

"Now, how to raise good Tulips of your own (which is the great secret) I shall here disclose. If you go to buy them of others you will soon empty your purse, for a good new Tulip will cost at least 30*s.* or 40*s.*, though the world is full of them, and within these few years has been worth 4*l.* or 5*l.* in London, and 10*l.* or 20*l.* in Paris; and some have paid much more in France.

"The way therefore to have the best perfected striped or party-coloured Tulips, and variety of such, is by sowing the seed of Tulips; but all seed will not produce good *ones*: no, not the seed of the best striped sorts themselves, which many will not believe; but experience hath given assurance of the contrary, and the reason is not altogether hid from us. In the fine curious striped sorts nature hath spent its stock and vigour to bring them to that delicacy, and there is little virtue left to come to the seed of such, and therefore such seed often produces plain yellowes and reds; and you shall see that your neat striped ones have either no seed or that which is but light and small. But the good hopeful seed is that which is yielded by strong vigourous Tulips, which are all of a colour; yet, every single coloured which affords strong seed will not produce good Tulips, such as the ordinary red, yellow, or white; but the single coloured from which you choose your seed must be either oranges, gridelines, or other shadowed colours, which wee cannot well tell what name to give to their colours, and their bottoms within must be either a fine celestial blew or sapphire coloured, either pale or deepe, or greenish. Those with blacke bottoms, or faint yellow, or none at all, are worth nothing for this purpose. The seed of those colours now spoken of must be chosen ripe, weighty, dry, and full, in July or August, as it is ready; the stalks full withered, and the seed case opening and rattling. Having gathered your seed when it is full ripe, and before it falls it blows away, sow it in very good sifted mold, in boxes or earthen pans, in September or October. In the spring they will come up like young Onyons. They must be taken out of the hot sun into some shady place as soon as these young leaves begin to wither, and then sift a very little fresh earth on them, and so let them stand abroad all winter. The next spring they will come up with small leaves, like such as they will ever after have. The second autumn take them up, sifting the earth, that you leave no root behind, and in September or October set them in fresh fine sifted earth again, and soe take them up yearly at the same time or thereabouts, and replant them again in October, in new fresh earth, and soe by this ordering they will bear flowers the fifth or sixth year. They never have more than one leaf till they bear flowers. When they bear, choose out the hopeful colours, and plant their roots by themselves. Having stood two or three years in a place, these single colours will become finely (panacheed, or) striped flowers. Those with blew bottoms will stripe white; those with greene bottoms with yellow. Few stripe perfectly in each leaf the first year, but when they do there is none or very little of the blew bottom to be seen. Commonly, the saddest dusky est colours, when they stripe, turn of a lighter colour, and soe, on the contrary, the paler reds turn deeper crimsons or purples; and the older the root is the more perfect the flower will be, if the soil and ordering be the best."

Home Correspondence.

The Ribstone Pippin.—In consequence of the statement concerning the original Ribstone Pippin-tree (p. 812), I wish to inform you that, at the particular request of the late Mr. Sabine, I examined the tree, which had no appearance of having been grafted, and sent to the Horticultural Society suckers from it; from which suckers the tree raised at the Chiswick Garden 18 years was obtained. No doubt was entertained by Mr. Sabine, after the receipt of the suckers, of their identity with the fruit-bearing portion of the tree. I also transmitted to him the account given to me by Lady Goodriche of the raising that tree from the seed of an Apple imported from Normandy, together with a sister seedling of inferior merit, which was then, and probably is still, on the Ribstone premises. The broken down stem was severed from the stump, and carried away by a violent gale of wind, after the head had rested a few years on the ground. —*W. Herbert, Deancry, Manchester.*

Gardeners' Benevolent Institution.—Observing in the two last Numbers of the *Chronicle* some strictures on the management of this Institution, and feeling an interest in that Society, believing it to be calculated to do much good, I beg to submit to the writers of those strictures the following remarks:—The fault that Mr. Whiting finds is, that there are more pensioners elected from the vicinity of London than from more distant parts of the country. But a little consideration will show that this is a necessary and unavoidable result; for the majority of the subscribers residing in or near London, it follows that they must recommend and vote for those of whom they know something, or whose personal appeals to their benevolence render their destitution more apparent. Again, London is the centre from whence gardeners go to fill the different situations in the country, and to which they return when out of place, or overtaken by misfortunes or old age; consequently the mass of destitution amongst gardeners lies near the metropolis. Further, those recommended from the more distant parts of the country are so by only one or two individuals, and those often non-subscribers—perhaps applying for a pension for an old servant who has lived with them till unfit for work; thus throwing a burden off themselves upon a Society to which they have never contributed. The committee have only a limited number of pensions to bestow, and whether they are bestowed upon individuals residing in Cornwall, Cumberland, or London, can make little difference, provided the persons are equally deserving and equally destitute: the same amount of human misery is alleviated. Besides, the committee have no control as to who shall or shall not be elected—they have simply their own vote to give. If there is any fault to be found it is with gardeners themselves, who do not join a Society established for their benefit; they have been applied to by letter to the number of 2000, and if only one-tenth of that number had responded to the call, the elections would have been in a great measure in their own hands. Further, any gardener who has subscribed for five years, upon producing the necessary recommendations, becomes a pensioner without election; so that they have everything wholly in their own power if they would only join the Society. Mr. W. P. Ayres points out another error in the management, viz., the price of the dinner-tickets; but this has, in reality, nothing to do with the Society. The dinner is a thing by itself, which may or may not take place, as thought most desirable. I believe that several members of the committee, if they only consulted their own inclination, would be averse to a dinner; but there are others who think differently, and who urge, that as other Societies acquire funds from the contributions of those who are gratified by being solicited to attend (and who otherwise would not join the Society), the committee would not be doing their duty did they not avail themselves of this source of increasing the funds of the Society. A dinner being agreed upon, stewards are appointed, and the arrangements are left in their hands. If Mr. A. has dined at the London Tavern, he must have found that an unlimited quantity of wine could not be allowed for even 15*s.*; each person will be allowed one bottle only. It is the lighting, professionals, and et ceteras, necessary to a public dinner, that becomes expensive; and if gentlemen are invited, they must have some enjoyment.* That these dinners are very absurd things I allow; yet they seem necessary, for some persons, without that stimulus to excite their benevolence, would not ever join a charitable institution devoted to their class. —*A Subscriber.*

Manure for Spinach.—On one occasion I had some Spinach sown in autumn on a very poor spot, without any manure having been applied. When it should have been fit for table in the spring, its leaves were all yellow, except the young budding ones; it was miserably poor, and was condemned to be pulled up and thrown away. It was, however, allowed to remain; the ground was well forked up and broken. It was raked and hoed, and then well watered; the soil was raked over daily. I then had a liquid compost prepared of several buckets of blood from the slaughterhouse, salt well stirred in, some wood-ashes and charcoal—filling the tub with water. This stood till my Spinach was making healthy growth; then, stirring up the mixture, and straining the thin part, it was poured to the roots—water was freely given before and after the application; the effect was wonderful. I had plants pulled up daily for use; the eradication effectually stirred up the soil where the fork could not be used. I tried by increasing degrees what forcing Spinach would bear in this way; morning, noon, and afternoon this liquid was applied, first and last resorting to the watering-pan; and every time the rich mess had been robbed, the butt was refilled with water and stirred, and once a week a bucket of fresh blood was added. Such was the growth of the Spinach, that numbers came to see it and my Bath Cos Lettuces, which were similarly nursed; the Spinach-leaves were larger than any dinner-plate. They were more like Rhubarb than Spinach, and of a fine Myrtle-green. My Melons and Cucumbers shared the same food, and with full success.—*A. W.*

Cropping of Fruit-tree Borders.—Shallow planting is now considered to be one of the most essential points by which we can obtain successful cultivation; but some gardeners, after bestowing the greatest care to plant their trees properly, have recourse to the injurious practice of cropping the ground over their roots; thus at once setting defiance to the effort made to keep them near the surface. I am aware that want of sufficient space for the culture of vegetables compels some gardeners to do this, but I imagine that the majority of them have it in their power to keep up a sufficient supply of culinary vegetables without having recourse to cropping the borders on which, at least, Peach and Apricot-trees are growing; their roots are destroyed by the operation of digging to the depth of a spade, and cropping exhausts the soil and forces them to descend still further, in order to obtain a sufficient supply of food. It is much more profitable to keep the ground over the roots mulched with rotten dung in winter and summer; this answers two purposes—it encourages the roots to approach the surface, and retains plenty of moisture during the summer season. A good watering occasionally, when the trees are in active growth, is, however, of great service, if the season is very dry. By this treatment many of the evils to which fruit-trees are subjected will be overcome. I may mention that the best crop of forced Grapes I have seen for some years has been produced by these same means.—*J. W.*

Brewing.—"A Farmer's Daughter" would much oblige a constant reader of the *Chronicle* if she would state how many pounds of Hops she uses to 6 bushels of Malt, and whether she puts into the boiler the decoction of the Hops only, or Hops and all.

Destruction of Small Birds.—Although it must be acknowledged that sparrows do much good by destroying hosts of caterpillars, grubs, &c., I think it remains a matter of considerable doubt whether the good thus conferred upon the gardener is not counterbalanced by the injury they inflict upon the buds of Currant and Gooseberry trees. Just now my trees are suffering much from these little busybodies, the buds being excavated to an alarming extent. I have tried every method I can think of, but cannot keep them away. If any of your correspondents will suggest a plan by which this may be effected, they will greatly oblige—*The Laird o' Cockpen.*

* If the stewards could calculate upon twice the number attending, they could reduce the price of the tickets probably one-third.

Pruning Forest Trees.—I observe that Mr. Billington and some of your other correspondents are at issue, as to whether the growth of timber proceeds from the ascending or the descending sap; and as this appears to me to be easily proved, I wonder that some one has not pointed out the method of doing this. Let the diameter of a young tree or branch in a state of vigorous growth be carefully noted the first week in May; then cut out a ring of bark, a quarter to half an inch broad, just above the measured part. On measuring this again in a month or two, it will be found, that whilst the diameter above the ring has increased very considerably, the increase is scarcely perceptible below: thus, in my opinion, proving Mr. Billington's assertion, that the increase is from the descending sap: for if, as physiologists tell us, the sap rises through the young wood, and descends between the bark and the wood, the circumcision of this ring would not prevent the ascent of the sap, although it would prevent its descent; and therefore, it appears to me that this ringing proves the truth of the physiological theory also. But here I must demur to going further with Mr. Billington. It may be true that timber grows best if all the branches are left on the tree—I am disposed to grant this, for the sake of the argument—but every one who uses timber knows that it is comparatively worthless when branched from top to bottom; the grain is twisted and distorted in all directions, and the timber is full of knots, which unfit it for any but the roughest and meanest purposes. "A. Thompson" (p. 795), as well as others, have shown very satisfactorily, that the value of a tree does not entirely depend upon the number of cubical feet contained in it, but in its suitableness for all useful purposes.—*Clitheroe, Dec.* 3.

Shanking of Grapes.—The theory which "An Amateur" has advanced as an explanation of one of the causes of the shanking of Grapes, is the same as was promulgated some 10 years back by Mr. J. D. Parks, of the Dartford Nursery, I think either in the Horticultural Society's "Transactions" or in the "Gardeners' Magazine;" and is sufficiently answered by the fact that many good growers of the Grape syringe their Vines early in a morning, and give no air until the moisture is dissipated, without being troubled with shanked bunches, or berries—to say nothing of a majority of the bunches, in most vineries, being under the shade of the leaves, and therefore beyond the influence of the sun's rays. It is premature to find fault with the tank-system of heating, unless we have better evidence than that advanced by your correspondent. In a majority of cases, when the cause of shanking does not originate in the border, I believe it may be attributed to the admission of cold currents of air on the young and tender bunch, careless handling when thinning, and other external injuries. Over-cropping is probably the most prolific source of bad fruit; and it is surprising that gardeners should persist in imposing upon the good-nature of their plants in forcing them to produce 20 lbs. of worthless fruit, when they might perhaps take 15 lbs. of first-rate quality. Clement Hoare's rule for cropping Vines is a good one, though perhaps under the mark; yet, if it was more acted upon, we should certainly both see and hear less of bad Grapes.—*W. P. Ayres, Brooklands.*

Ice.—Having no ice-house here, we last year made a large heap of ice above ground, and thatched it 18 inches thick. It has kept well until this time. This year we are adopting the same plan, with the difference of thoroughly watering the heap as we proceed. Is not the plan a bad one? and instead of causing the heap to become a solid body, will it not have the very contrary effect?—*J. Greenshields.* [No. But we see no advantage in watering it. It should be pounded fine.]

Advantage to Gardeners of a Knowledge of Vegetable Physiology.—Every gardener in this age of science, who aspires to anything like eminence in his profession, should know something of Vegetable Physiology. He ought, at least, to be so far acquainted with its true principles, as to be able to conduct his operations with some degree of certainty. Many will say "I am generally successful in my undertakings, without knowing anything of physiology, and I am acquainted with many good gardeners who scarcely know the meaning of the word." This may be the case; but is it not far more business-like, more systematic, and more advantageous in every way, to be able to calculate pretty correctly the result of an operation, than to be working in the dark? But admitting that the gardener can conduct his operations without a knowledge of the various organs of plants and their functions, it is surely preferable to understand the beautiful economy of the vegetable fabric, to comprehend how the crude fluid is absorbed by the roots, and conveyed through the intricate ramifications of tubes spread out to the action of the atmosphere, in the leaves, and to watch it returning a nutritious fluid for the nourishment of the several parts of the plant. Surely it must induce us to take a greater interest in plants, to watch the many beautiful contrivances of nature which insure the reproduction of each species, to behold the exquisite adaptation of each individual to its assigned place on the surface of the globe, whether beneath the sun of the tropics, the regions of perpetual snow, or the more genial climate of the temperate zone, or the many varieties of situation which each climate affords. In each and all, we behold subjects peculiarly adapted to their several situations, and each offering abundance of matter for our study and contemplation, and from which we may derive much that is useful and instructive. Linnæus, when instructing his pupils, is recorded to have merely placed his hand upon the turf on which they were standing, and to have pointed out to them the many specimens growing in that little space worthy of their attention. In fact, almost every spot offers something capable of arresting our attention.

> "Not a plant, a leaf, a flower, but contains
> A folio volume. We may read, and read,
> And read again, and still find something new—
> Something to please, something to instruct
> E'en in the noisome weed."

In no branch of gardening, perhaps, is a knowledge of physiology more requisite, or more certain of directing our operations with success than in propagation. It is to the operator what a knowledge of navigation is to the mariner in steering his vessel through a dangerous sea. A person unacquainted with either may perform their work in both instances correctly; but there is a want of confidence, and the results, be they what they may, are but the offspring of mere chance. In looking over the rising generation of plants, intended by their possessors for the next year's decoration of their flower-gardens, while in the cutting-pots, how many are the instances in which failure is certain! or, at best, a poor sickly plant will be the result, arising solely from a want of determination in the selection of the cutting. And this discrimination can best be exercised by a knowledge of the structure of the part selected for the cutting; whether it contains those tissues from which roots are to be formed in sufficient abundance, or which part is most calculated to repay us by the production of a vigorous and healthy plant. That this can, in a great measure, be calculated upon from the appearance of the branch selected, admits of no question. The gardener, surrounded as he is by the many beautiful processes in the great laboratory of nature, must, before he can enter fully into the spirit of the thing, be a scientific man; and I trust to see the day (although much must co-operate to bring about such a state of things) when a knowledge of the sciences which most directly bear upon his profession, will be looked upon as an indispensable qualification in him. But I would not be misunderstood: the mere scientific man can never be a good gardener. Science can only be looked upon as an assistant. A man may be a good gardener (and undoubtedly there are many), who knows nothing of the scientific portion of his business. A long and careful practice, with a keen and perceptive observation may, in a great measure, dispense with science; but it is bad policy to occupy a long series of years in obtaining a knowledge which might be gained in a far shorter period; and by the aid of science this can be effected. It is by practice alone that many of the operations of the garden can be thoroughly carried out with success; but by science we understand the general principles of everything pertaining to gardening, and by it we can direct our operations with a confidence which, in the absence of such a knowledge, is mere hazard. Let the young gardener, however, always bear in mind that nothing will compensate for want of practice and observation; blend these with science, and success is certain. —*Walter Wakefield.*

Liquid Manure applied to Carnations.—I mixed Peruvian Guano with rain-water at the rate of half an ounce to a gallon, with which the pots were watered once a week. Another quantity of pots was watered with Potter's liquid guano, mixed, if anything, a little weaker than he directs. All did well. I never had such healthy plants, nor so fine a bloom; nor had I ever so few run flowers. I think manure can hardly be the cause of running, for I potted some Rose-flakes, which were always apt to run, in a mixture chiefly composed of rotten dung and soot which had been exposed to the weather for a year; they grew well, and bloomed clean and fine, as also did some purple flakes in the same mixture. Pinks in pots, in an eastern aspect, watered always once, and often twice a day with a mixture of old manure and soot with rain-water, laced remarkably well; whilst others, planted in a bed of extra rich compost, under a south wall, the autumn previous, did not lace so well, although they grew luxuriantly. Perhaps the regular moisture affected the lacing as much as the manure.—*G.*

Humphreys's Compound.—This agreed very well with Polyanthuses and Pinks in pots, and next to that superphosphate of lime, made by burning bones, and steeping them in sulphuric acid and water, seemed to produce the most visible effect in a short time, the plants being top-dressed with it.—*G.*

Passiflora quadrangularis.—This plant is generally cultivated for the sake of its beautiful flowers and climbing habit, but it may also be made to produce large and excellent fruit. The treatment required to fruit the plant is, however, somewhat different from that usually employed to make it flower only. It may be grown in the stove, or better, perhaps, in an intermediate house between the stove and greenhouse. It is necessary to the perfect cultivation of the plant, that it should grow in a border in the inside of the house, rather than in pots, however large. If no other situation presents itself, a border may be made beneath the path, taking care to leave a space of 3 or 4 inches between the surface of the soil and the stones, so that there may be a free access of air, and that water may spread equally over the surface of the soil and moisten it thoroughly. Whatever may be the situation of the plant, particular attention must be directed to the drainage, which must be as efficient as possible. As the plant may have to remain some years in one situation, five or six barrowfuls, or even more, of good soil, composed of three-fourths good loam and the rest leaf-mould, should be prepared in a very rough state. A spare rafter, or any such place near the glass, will do exceedingly well for the plants to be attached to. If young when turned out, the plants should not be allowed to bear flowers or fruit the first year. One, or at most two branches should be allowed to grow, and after they have extended 10 or 15 feet, they should be stopped and should not be allowed to put forth any laterals. During winter no water should be given unless the plants droop. Some time in February the branches must be well cut back; and if it is necessary to leave any length of stem between the ground and the glass, all the buds, excepting three or four at the top of each branch, must be rubbed off. The number of branches allowed to grow in the second year must be determined by the strength of the plant; from two to six being the usual number. Advantage should be taken of the first flowers that open to fertilise the stigma, for fructification will not always take place naturally. From one to three fruit are sufficient on each branch; if a greater number are allowed to remain they will be small and of little value. The fruit-bearing branches may be stopped at the distance of 5 or 6 feet above the fruit. Some cultivators, however, do not stop the branches at all, but I consider it better to stop them, but in either case no laterals must be allowed to grow on any part of the plant; for no fine fruit can possibly be obtained if the plants are allowed in any way to run wild. Treated in this way, *P. quadrangularis* will frequently produce fruit 4 lbs. in weight; and though not ranking as a first-class fruit, it makes a rather novel as well as a useful addition to the dessert, at which its pulp is eaten with sugar and wine. None of the other species of Passiflora bear so large fruit as quadrangularis; of others, edulis and laurifolia are amongst the best. Unlike quadrangularis the branches of these smaller-fruited species must not be stopped, and they will continue to flower and fruit for several months in a stove. The fruit is eaten with the same ingredients as the larger kind, and has a flavour agreeable to most palates. It is necessary to be particularly careful in selecting good varieties, for there are several spurious kinds in cultivation. The best way is to get plants from old ones which are known to bear good fruit.—*J. W. Jones, Royal Botanical Garden, Kew.*

Honeycomb Labyrinth.—A honeycomb labyrinth was discovered a few weeks ago in the upper part of an antique side-wall of Nateby Hall, near Garstang, the residence of J. Stuart, Esq. At what period this insect labyrinth had been established, is unknown. The longest winding passage in it was about 6 feet in length, the widest part was about 18 inches across, and the highest part was about 20 inches in height. The entrance was from the centre to the outside of the roof, which is high, and concealed from view by branches of lofty trees. The discovery was made by a person in an upper room, who from time to time hearing a noise, communicated the circumstance, and an aperture was made in the wall of the room. In a short time the hive was discovered, and the whole of the bees destroyed; their labyrinth was minutely examined, cut down, and removed by making a number of apertures in the wall. The weight of the honey and the comb was 110 lbs. It appears that they had first commenced to build in the centre, as about two feet of the honey and the comb in that part was black; in other parts it was excellent. It is stated by some writers that there are bees which produce black honey, but from this it would appear that it is age that turns it black.—*M. Saul, Fort Green Cottage.*

Contrast between English and Irish Weather.—I have just learned from Mr. Boylan, gardener to the Earl of Kenmare, Killarney, that many of the Rhododendrons are now in full flower, and he has also a Yucca gloriosa with seven flower-stems, also in full blossom. In this neighbourhood we have still in bloom Dahlias, Leonotis Leonurus, and many varieties of annual flowers, as well as Apple-trees and Narcissus. This contrasts strangely with the account of the weather on your side of the Channel, as recorded in the *Chronicle* of the 7th inst.—*John Haycroft, jun., Victoria Nursery, Cork, Dec.* 9.

Birch Coppice.—If "Romseyoniensis" had stated at what time of the year he cuts over his Birch stools, perhaps the cause of their dying might have been explained to his satisfaction. In the mean time, however, I would advise him, if it has not hitherto been his practice, to defer cutting the produce from the Birch stools, or the cutting off young plants or trees, to form stools, till the buds are fully expanded, or rather broken into leaf. This, I have no doubt, will prove a cure for his failures. Will "Romseyoniensis," after he has tried this plan, favour the readers of the *Chronicle* with the result?—*W. Billington.*

Bees.—When I recommended bee-keepers to use large hives, I did not wish them to believe that, by putting a small swarm into a large hive, a greater quantity of honey would be obtained at the end of the first season, but simply that the bees would, during the second and following seasons, gather more honey, hatch more brood, and send out larger colonies, &c. Surely England is more able than Wales to send out large colonies to other countries. My brother informs me that, in 1842, he realised from his apiary, consisting of 7 stocks, 19*l.* 10*s.*; in 1843, from 8 stocks, 20*l.*; and in 1844, from 11 stocks, 20*l.* If any apiarian has made more of his bees during the last three years than the above sums, I shall be obliged by his informing me how he manages them. Mr. Wighton's possessing a bit of worker's comb, containing young drones, does not disprove the assertion that bees' eggs are transmutable. I have long ago seen drones bred in workers' cells. When there are no drone-cells in a hive the bees generally hatch a few drones in workers' cells, about the time in which the first swarm leaves the hive. These drones are bred for the purpose of impregnating the young queens. Bees will not breed drones when the bees have a timely impregnated queen, no drone's cells, and plenty of room. The transmutability of bees' eggs has already been so well proved in the

Chronicle, that it is a misspending of time to say anything further on the subject.—*S. Pettigrew.*

Baskets round Flower-borders.—As the Article (p. 622) descriptive of the noble gardens at Hewell appears to have been written by a person of some taste in gardening matters, I am rather surprised that when he was condemning the "wicker-work" which gives the appearance of "huge baskets of evergreens and flowers" to the beds on the lawn at that place, he did not advise its removal from the garden altogether, instead of recommending its use for beds of scarlet Pelargoniums and other plants. If it is wrong to use the wicker-work as it is at present employed, on what principle would "R. G." justify its use on the same lawn for beds of flowers? In my opinion wicker-work, or indeed fancy edgings of any kind, are altogether out of place when surrounding flower-beds; and though we see such things in many places where one would expect to find an exemplification of better taste, yet they are not the more to be tolerated on that account. In the garden of a noble Countess not many miles from the place where this is written, the flower-beds are edged with cable rope nailed on strong stakes about 18 inches high; and to render such an arrangement more enduringly objectionable, the rope is regularly every spring dressed over with tar. At Blenheim, and if I remember right, at Chatsworth, some of the flower-beds are edged with dwarfed oak trees, which is most assuredly a singular fancy—to make the monarch of the woods an edging for flower-beds! Now, although fashion—which may be in gardening matters designated the whim or caprice of individuals—may sanction such things, there cannot be two opinions about their being in direct opposition to good taste, though not so much so, edgings of wicker-work. If basket-work must be admitted into garden scenery at all, let it be as pens for wild fowl, and not as peaceful habitations for the cultivation of plants.—*Argus, Newmarket.* [It would not be very difficult to answer these objections, in which we need hardly say that we do not concur.]

Miscellaneous.—*Mr. Thomas Fullam*, of Sutton, inquires what the difference is between Mr. Dale's system of growing Pine-apples and that of Mr. Hamilton; and whether that of the latter is different from the way in which Pines produce fruit in their natural state? He remarks that the Pine in its native country produces suckers which bear fruit in succession until they become so crowded that they break down in large masses of a cartload at a time. Finally, he states that the best flavoured fruit from plants in a wild state, is produced from those growing in sand.

Reviews.

The Gardeners' Almanack, for the Year 1845. By G. W. Johnson, Esq.

THIS is what it calls itself, and something more. It is exactly what such a publication should be—full, accurate, and novel. Ninety-six pages of very closely printed matter are crowded with information of all sorts, upon subjects of horticultural interest, besides which there is the usual information contained in a pocket-book. In short, we can recommend it to anybody who wants a Garden Almanack, as the best of its kind.

Some extracts from it will give the reader an idea of the author's mode of treating his subjects:—

"*The Allotment System.*—Many years since, the present writer advocated, to the best of his ability, this best of all aids to the labourer, and he is glad that this improvement in our social system has at length so far progressed, as to have attracted the attention of the legislature, to whose judgment a Bill, regulating and promoting parochial allotments, will be submitted by the Hon. W. Cowper. We implore every member of that legislature to give it his support, and we give our testimony in concurrence with the evidence produced before the late Committee of the House of Commons, that an allotment of land to every cottage is the most efficient mode of improving the condition of the labouring classes. Indeed, it requires no evidence to sustain its merits, for all experience testifies that a man, with the occasional help of his wife, can, during his over-hours, cultivate a quarter of an acre—and that this space will nearly supply with Potatoes and other vegetables, throughout the year, the parents and four children. This is a fact beyond the reach of dispute. Then, we ask, what argument can prevail against such a space being the least allotted to every cottage? We have heard it said that if men grow Wheat and Barley, it will prevent detection should they steal their master's:—to which we reply, that supposing it does prevent the detection of one theft, yet by giving a good supply to every cottage, you save hundreds from the temptation to thieving. Again, we have heard it said that the labourer who toils in his garden, expends the strength which should be husbanded for his master's service:—to which cold-blooded dictate of a heart worthy of the slave-owner we reply, that all experience demonstrates that those labourers who devote their leisure to their own gardens, are invariably the best characters and the best workmen in a parish. But, suppose that the error was truth, and that the man who dug in his own garden could not labour quite so vigorously on his hirer's land—yet, if that garden kept him from the poor's rate, the farmer would be more than a gainer still; and it is a truth, to which we have ample testimony, that allotments of land do keep the labourers from requiring parochial relief. We have no space to go into detail, but we implore every legislator, every country gentleman, to act up to the spirit of the 31st Elizabeth, cap. 7, which prohibited a cottage being built unless four acres of land were appended to it. Let every cottager have no less than his rood of land—and we ask it, because the language of the committee we have noticed we know to be the language of truth, when it says, 'The garden allotment system is a powerful means of bettering the condition of the poor; nor are its benefits obtained at the expense of any other class, nor accompanied by any corresponding disadvantage.'"

"*Steeping Seeds.*—The most ill-founded idea that has been suggested by the minds of those who have been labouring to improve the arts of cultivation during the past year (1844), is that by steeping seeds in certain solutions, the vigour and fecundity of the plants to which they give birth might be promoted. A certain degree of heat, oxygen gas, and water, are all the requisites for germination; and until this process has commenced, no liquid but water, at common temperatures, will pass through the integuments of a seed. So soon as germination has commenced, this power to exclude foreign fluids ceases, but the organs starting into activity—the radicle and the plumule—are so delicate that the weakest saline solutions are too acrid and offensive for them. So utterly incapable are the infant roots of imbibing such solutions, that at first they are absolutely dependent themselves for their very existence upon the seed-leaves, and if these are removed the plant either makes no farther advance, or altogether perishes. Many years since we tried various menstrua to facilitate the germination of seeds, but, with the exception of those which promoted the decomposition of water, and the consequent more abundant evolution of oxygen, we found none of any efficiency. As to keeping the seeds in saline solutions until they germinated, we never, certainly, carried our experiments so far as that, and we shall be most astonished if any other effect than injury or death to the plant is the consequence. Such has been the result in the Horticultural Society's Gardens, where the seeds of Lupinus Hartwegii were made to germinate in a weak solution of phosphate of ammonia."

Before we dismiss Mr. Johnson's useful book, we must not forget to correct an error into which he has fallen, in attributing (p. 44), some very curious experiments on the power possessed by muriate of lime of retaining moisture, to Dr. Lindley. They were really made by Mr. Edward Solly, in the course of his examination of various facts brought under the notice of the Chemical Committee of the Horticultural Society.

The Garden Almanac. By G. Glenny. Westley. TRASH!

NOTICES OF NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

GAYLUSSACIA PSEUDOVACCINIUM. Bilberry-like Gaylussacwort. (*Hardy Greenhouse Shrub.*) Vaccinaceæ. Decandria Monogynia.—The genus Gaylussacia, so named after M. Gay Lussac, the eminent French chemist and philosopher, differs from Vaccinium in the same way as Arctostaphylos from Arbutus—it has but a single seed in each cell. The species are chiefly found in Brazil, where they are common, Peru, and the North of India, and among them are several which, as this species shows, would be worth introducing to cultivation. G. pseudovaccinium is stated to be a native of sandy, open plains in Brazil. Auguste de St. Hilaire says that he found it on the coast from the city of Caravellos in the province of Porto Seguro as far as the island of St. Catharine, and that it forms a shrub from 1 foot to 2½ feet high. At least it is to be presumed that this is the plant he means, although he describes the corolla as somewhat narrow, and the ovary as five-celled, with one-seeded cells; for the flowers are much too globular, and M. de St. Hilaire adds that the fruit of his plant has 10 ribs when dry, in consequence of its containing 10 seeds; whence it is evident that his account of the ovary is erroneous. It is a hardy and very pretty greenhouse shrub, which should be grown in a mixture of sandy peat and leaf-mould, and treated in the same way as Cape Heaths. It may be increased either by seeds or by layers. Seeds should be sown in pans filled with sandy peat about February, and covered with a bell-glass. The layering should be effected before the plant commences its fresh growth.—*Botanical Register.*

TETRATHECA HIRSUTA. Hairy Tetrathe[illegible] (*Greenhouse Shrub*). Tremandraceæ. Octo-Decandria Monogynia.—Where the name has been published which this pretty plant bears in our gardens I have failed to ascertain. It is certainly no other than Tetrathecа hirsuta, and by no means a Tremandra, if, as seems clear, the essential character of that genus consists in its anthers not terminating in a tube nor opening by a pore at the point. Messrs. Rollissons received it from Baron Hugel in the summer of 1843, and flowered it last March. It is a very nice greenhouse plant, gay with purple starry blossoms. It grows freely in a compost of peat loam and sand in equal proportions, and if a few potsherds are mixed with it so much the better. In summer plenty of air and water should be given, and shade in sunny weather. In winter the plant should be placed in some airy part of the house, where it will be secure from damp. Fire-heat should not be applied, except to keep off frost. It may be propagated by cuttings in the usual way.—*Bot. Reg.*

Garden Memoranda.

Horticultural Society's Garden, Turnham-Green.—The Chrysanthemums here have been a failure this season, probably in consequence of their having been put into the conservatory too early and placed too far from the glass there. The cuttings were struck about the end of March, in a cold frame, and were potted off and regularly shifted from 60s into 32s, 24s, 16s, and ultimately into 8s. The soil employed was a mixture of loam, peat, and well decayed cow-dung in nearly equal proportions. After receiving the last shift, which was about the beginning of August, the plants grew very rapidly, and soon formed handsome bushes. They were watered with manure water once a week from the beginning of August until the middle of October, when they were removed from the open air into the conservatory and placed along the side of the pathway. Here they continued growing instead of immediately setting for bloom, and small ill-formed flowers, showing the centres in many cases, was the result. Had the plants been weakly we should have attributed the cause of failure to late stopping, which is an error into which many fall; but this is not the case, for the plants exhibit good cultivation as regards vigorous growth, having a multitude of strong stems covered with healthy dark-green foliage to the very root. Want of sufficient air and light, which Chrysanthemums in particular require, and without which they cannot be expected to succeed, seems to be at the root of the evil, to which cloudy wet weather occurring when the plants were placed in the house after a hot dry summer, has doubtless contributed. In the conservatory a plant of Bonaparteа juncea, now called Littæa geminiflora, has been in bloom for at least three months. The flower-stem is upwards of 15 feet in height. It commenced producing its dull yellow blossoms about 3 feet above the plant, and is now in full bloom beyond the middle of the stem, the flowering gradually progressing upwards. The two flower-spikes on Lælia superbiens in the large stove, are already 3 feet in length, and promise to flower well. The Aristolochia gigas, trained along the roof of this house, has since the 26th of October, produced 163 fully expanded flowers, besides many others which have not opened. It proves to be a valuable stove climber, the only demerit connected with it being its bad smell, which, however, when it is trained on the roof of a stove is hardly perceptible. In this house was also in bloom a new Gesnera, having flowers somewhat resembling those of Achimenes picta, or pedunculata. It was sent by Mr. Hartweg, who found it in the woods near Bogota. In one of the pits belonging to the hardy department was a seed-pan containing young plants of the Tussac-grass, which has vegetated freely in a peaty soil, in a greenhouse temperature. Near this was a small plant of Cryptomeria japonica, from Mr. Fortune, who sent it from Shanghae. This is said to be a tree like a Cypress, of great beauty, and attaining a height of between 40 and 50 feet; and if it prove to be hardy, as it is expected to be, it will form a valuable addition to Conifers. In the orchard department preparations are now in progress for renewing the worn-out trees on the Peach wall. The Pears which grew by the side of the walk in front of the border are being taken up; the best of them are already planted in a row along the east side of the kitchen garden. Although it is upwards of 20 years since these trees were first planted, yet, being on Quince stocks, they removed with an abundance of fibres. The border is being trenched for the reception of the young Peach-trees, and a quantity of North Hyde loam has been procured for the purpose of mixing with the soil in which the trees are to be planted.

Stackpole Court, near Pembroke.—Phormium tenax is grown on rather a large scale here, and to what may be considered near perfection, its foliage averaging, over the whole plantation, from 6 to 7 feet in height. A great annual weight could be procured if a ready mode of converting it could be hit upon; and we should feel obliged if any of the numerous correspondents of the *Gardeners' Chronicle* would furnish some information on the subject.—*Dec. 9.*

Miscellaneous.

New Uses of India-rubber.—About three years ago its chief and almost only use was in the manufacture of Macintosh's waterproof cloth, the fabrication of some surgical apparatus in which elasticity and pliability were the objects desired, the rubbing out of black-lead pencil-marks from paper, and a few other minute and unimportant applications. Now, however, this substance is employed in some highly important branches of our manufactures, and has become a valuable agent in the arts and sciences—showing what an extensive field the rapid advance of science may open up for the appliance of materials hitherto considered as next to useless. From its peculiar elasticity, its impermeability to air and water, its being soluble only in naphtha, and from its great durability, it has been successfully employed in the fabrication of various cloths, besides that of Macintosh; for air-cushions, safety-belts and jackets; ligaments and bandages for gloves, stockings, braces, and other articles of dress; for boots, stoppers for bottles, and numerous other purposes. With these appliances most of our readers may be familiar; but few may know, or might expect, that it would be employed as a pavement for stables, lobbies, public halls, and the like; that it is now being used in the construction of life-boats; and that it is also proposed to use it extensively in the fitting up of our men-of-war. The Elastic Pavement Company have lately erected machinery for the preparation of the material for these important purposes, and can produce it, it seems, at a price sufficiently moderate to admit of its general adoption. As a pavement for stables, the caoutchouc preparation is said to be unequalled, preventing the lodging of stale matters, and their consequent noxious exhalations; requiring little litter, and preserving the knees and other parts of the horse from injuries which are apt to be received in stone-paved stables. By a little precaution, the ammonia, which now exhales to the injury of the horses' health, may be collected and sold as a manure, at from 2*l.* to 3*l.* per horse per annum. The stables of the Commissioners of Woolwich dockyard have been paved with this material for upwards of two years, and are allowed to be superior in point of cleanliness, freedom from smell, and healthiness, to what they were previous to the laying down of the elastic pavement. It has also been laid down in the Admiralty courtyard, and the carriage entrance court to Windsor Castle, where it has given much satisfaction. "With respect to its application to marine purposes," says the *Railway Gazette*, "a life-boat is now being constructed on the Company's premises (34 feet length of keel, and 12 breadth of beam), which, with the exception of the keel and some iron braces, will be entirely formed of

India-rubber and cork planking. She will weigh but one ton and a half, an ordinary life-boat weighing three tons; and it is the opinion of all naval men and engineers who have seen her, that it will be almost impossible to sink her under ordinary circumstances, and that, when driven on a rock by the action of the waves, she will rebound like a ball, without fracture. It is also proposed to use the caoutchouc preparation for an inner lining between the guns in war-vessels, to prevent the effects of splinters'; for hammock-nettings and bulwarks, to save the crew from canister, grape, &c.; and for other useful though less obvious purposes." Such are the numerous purposes to which human ingenuity can apply a single, and to all appearance an insignificant substance —the exuded sap of a tree; showing that science not only supplies our more obvious wants, but creates others, and calls into use hitherto neglected materials to supply them. Nothing in nature is useless; if we cannot now see its value, let us rest assured that the time will come for its profitable application.—*Chambers's New Edinburgh Journal.*

Allotments.—Among other instances of great success in carrying out this system, may be named the village of Pytchley, in Northamptonshire. In that parish are 56 allotments, and their crops have been "superb," to use the words of a correspondent. One man had 7½ bushels of clean Wheat off his half rood, and a large crop of Potatoes off the other half rood. Many others were scarcely inferior. *Pergite queri!*

The Chocolate Tree and its Uses.—What is generally called Cocoa is merely the berries of Theobroma Cacao, pounded and drank either with water or milk, or with both. Chocolate is a compound drink, and is manufactured chiefly from the kernels of this plant, whose natural habitat would seem to be Guayaquil, in South America, though it flourishes in great perfection in the West Indies. It grows also spontaneously and luxuriantly on the banks of the Magdalena. Mr. Schomburgk, in his recent expedition into the interior of British Guiana, found the country abounding in Cocoa, "which the Indians were most anxious to secure, as the pulpy arillus surrounding the seed has an agreeable vinous taste. Singular to say, however, they appeared perfectly ignorant of the qualities of the seed, which possesses the most delightful aroma. Mr. Schomburgk states, they evinced the greatest astonishment when they beheld him and Mr. Goodall collecting these seeds and using them as Chocolate, which was the most delicious they had ever tasted." The height of the Cocoa shrub is generally from eighteen to twenty feet; the leaf is between four and six inches long, and its breadth three or four, very smooth, and terminating in a point like that of the Orange tree, but differing from it in colour; of a dull green, without gloss, and not so thickly set upon the branches. The blossom is first white, then reddish, and contains the rudiments of the kernels or berries. When fully developed, the pericarp, or seed-vessel is a pod, which grows not only from the branches, but the stem of the tree, and is from six to seven inches in length, and shaped like a Cucumber. Its colour is green when growing, like that of the leaf; but when ripe, is yellow, smooth, clear, and thin. When arrived at its full growth, and before it is ripe, it is gathered and eaten like any other fruit, the taste being subacid. Chocolate, so called, and so prized both in the Spanish Continent and in the West Indies, never reaches Great Britain except as a contraband article, being, like nearly all colonial manufactured articles, prohibited by the Custom-house laws. What is generally drank under that name is simply the Cocoa boiled in milk, gruel, or even water, and is as much like the Spanish or West India Chocolate as vinegar is to Burgundy. It is, without any exception, of all domestic drinks the most alimentary; and the Spaniards esteem it so necessary to the health and support of the body, that it is considered the severest punishment to withhold it, even from criminals; nay, to be unable to procure Chocolate, is deemed the greatest misfortune in life! Yet, notwithstanding this estimation in which it is held, the quantity made in the neighbourhood of Carthagena is insufficient for the demands of the population, and is so highly priced that none is exported but as presents! The signs by which good Chocolate or Cocoa is known are these:—It should dissolve entirely in water, and be without sediment; it should be oily, and yet melt in the mouth; and if genuine and carefully prepared, should deposit no grits or grounds. That made in the West Indies and in some parts of Cuba is dark; but that manufactured in Jamaica is of a bright brick colour, owing to the greater quantity of arnatto which is used in the preparation, and which, I think, gives it a richer and a more agreeable flavour. In an economical point of view, Chocolate is a very important article of diet, as it may be literally termed meat and drink; and were our half-starved artisans, over-wrought factory children, and rickety millinery girls, induced to drink it instead of the innutritious and unwholesome beverage called Tea, its nutritive qualities would soon develop themselves in their improved looks and more robust constitution. The price, too, is in its favour, Cocoa being 10*d.* per pound; while the cheapest black Tea, such as even the Chinese beggar would despise, drank by milliners, washerwomen, and the poorer class in the Metropolis, is 4*s.* a lb., or 310 per cent. dearer, while it is decidedly injurious to health. The heads of the naval and military medical departments in England have been so impressed with the wholesomeness and superior nutriment of Cocoa, that they have judiciously directed that it shall be served out twice or thrice a week to regiments of the line, and to the seamen on board Her Majesty's ships, and this wise regulation has evinced its salutary effects in the improved health and condition of the men. Indeed, this has been most satisfactorily established in Jamaica among the troops; and a remarkable fact corroborating this statement is, that by returns to the Horse Guards, it is shown that only one death took place at Newcastle Barracks, in that island, out of a force of 700 men, for the quarter ending Sept. 30, 1842; and the same may be asserted of other regiments in the West Indies, and of the seamen in Her Majesty's ships on the coast. But the excellent qualities of Chocolate were known not only to the Mexicans and Peruvians, from whom, as a matter of course, the Spaniards acquired a knowledge of its properties; but European nations also acknowledged its virtues. The Portuguese, French, Germans, and Dutch, considered it an exceedingly valuable article of diet, and Hoffman looked upon it both as a food and a medicine. In his monograph, entitled "Potus Chocolate," he recommends it in all diseases of general weakness, macies, low spirits, and in hypochondriacal complaints, and what since his time have been termed nervous diseases. As one example of the good effects of Cocoa, he adduces the case of Cardinal Richelieu, who was cured of cremacausis, or a general wasting away of the body, by drinking chocolate. Liebig and other chemists have demonstrated beyond question that no part of an organ which possesses motion and life is destitute of nitrogen:—"All parts of the animal body which have a decided shape, which form parts of organs, contain nitrogen;" and the chief ingredients of the blood contain 17 per cent. of nitrogen, and no part of an organ less than 17 per cent. It follows, therefore that nitrogen is that principle of the body which, being in the greatest quantity, and pervading all tissues, is that most frequently wasted, and most frequently in need of renewal. This must be admitted. It follows, then, that those substances which possess this principle in the greatest quantity in a given bulk, are those which must be best calculated to renew that which has been lost or wasted by the operations of the body. Now caffeine (the principle of Coffee), and theobromine (the principle of Theobroma Cacao), are the most highly nitrogenised products in nature, as the following analysis will show:—Caffeine according to Pfaff and Liebig contains—

Carbon	49·77	Nitrogen	28·75
Hydrogen	5·33	Oxygen	16·12

Theobromine, according to Woskresensky, contains—

Carbon	47·27	Nitrogen	35·39
Hydrogen	4·54	Oxygen	12·80

—*Dr. Binns, in Symmonds' Colonial Mag. (abridged).*

Upon the Degeneration of Brussels Sprouts.—The degeneration of this plant has been much discussed. It remains unchanged in the soil of Brussels, and also in the environs of Louvain, but at Malines, which is at equal distances from these two towns, and where every possible care is paid to the cultivation of vegetables, yet, after the first generation, it loses its peculiar character. It does not, however, appear that any particular soil, or special precautions, are necessary for its cultivation, for these sprouts grow in Brussels and its environs, in all kinds of soils and situations. According to M. Van Mons, its degeneration had been very sudden at Malines. "The plants which I sent there," says he, "and which were produced from true seed, made shoots exactly like those which are seen at Brussels; but the seed which was obtained from it produced plants which made shoots, not in little compact heads, but open, with long drooping leaves; so that after the third generation, it entirely lost its primitive character. The same phenomena of degeneracy have also been observed in Germany, where, at different times, they have tried to cultivate Brussels sprouts. At my request," continues M. Van Mons, "they sent me some seed, gathered from the degenerated plants. I sowed it by itself and as the plants grew, I observed that they showed the same character of degeneracy that they did at Malines. I allowed them to seed, which I carefully gathered. The second time of sowing they came nearer their original character, but the heads were still not very compact, and did not shoot a second time, as the true sort does. At the third generation, the plants had regained all the merits of their original character." These experiments, and their results, certainly deserve our attention; but as we have said before, the influence of the pollen extends to such great distances, that the re-establishment of the sprout might be attributed to fertilisation by the pollen of sprouts growing in the neighbourhood. Besides, it is easy to explain the degeneracy of a plant, if external influences become unfavourable to it; but that a plant once degenerated may regain its original characters by mere local influences, would require more than one experiment to prove.—*Journal d'Horticulture de Bruxelles.*

On the Advantage of the Use of Carbonate of Soda in the Preparation of Coffee (by Professor Pleischl).—It is a fact well known in Prague, that the water of the wells in that town is better adapted for use in making coffee than the river water; comparative analyses of the water indicate that this depends on the carbonate of soda contained in the former. Pleischl found this opinion corroborated by the fact, that a small quantity of the salt added to Coffee improves its flavour, and advises consequently the addition of 43 grains of the pure carbonate to each pound of roasted Coffee, as an improvement to the flavour and also to the therapeutic effect of this beverage, as it neutralises the acid contained in the infusion. —*Pharmaceutical Journal.*

New Zealand Coal.—Some interesting specimens of coal have been recently brought over from New Zealand. The coal traverses, in seams, the seagirt rocks of the island, and the specimens that have come to hand are nodules of a moderate size, composed of carbonate of baryta, coal, and sulphuret of iron. The coal itself is exceedingly black, clean, and glistening, is easily frangible and appears to be little, if anywise, inferior in quality to the best Wallsend or Lumbton Main samples in the London market, and far superior to the Burdwan coal of India. The proportion of coal to baryta and sulphuret of iron, in the above samples, is as 13 to 20.—*Daily Papers.*

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

Where practicable, plant-houses ought to be covered with mats or some other covering in severe weather, particularly the stove. The steady high temperature maintained in Cucumber-pits could not be effected without thick coverings; slight skeleton frames made to fit the glass sashes, and covered with some waterproof material, are most convenient, and in the long run the cheapest. Where mats are used they should be sewn together, for the convenience of being rolled off and on easily. All stove plants, except a few Orchidaceæ and some bulbs, &c., should now and for the next six weeks be quite at rest, and in that state 55° is high enough for them in cold weather. No more water should be given at the roots than what will keep their leaves from flagging, but the atmosphere ought to be kept more or less moist. A high dry atmosphere is much more prejudicial to stove plants than any cold they can suffer in a temperature above 45°.

Conservatory.—About 45° is the best temperature for this house in cold weather; not but that the generality of half-hardy plants will outlive the winter if the frost is kept from them, but 40° is high enough for a conservatory not attached to sitting-rooms, and only used for the purpose of wintering large specimens without plants in blossom. A few good stove plants and a forcing-pit are essentials to a good conservatory in winter. See that the fire place, flues, and pipes act properly, as we often hear of accidents arising from such sources. Where the heating apparatus is barely sufficient to keep up the required temperature, accidents are more likely to follow. Sometimes plants are injured at this time by being placed over where the pipes pass under the pavement, &c.; in such cases an empty pot placed under them would lessen the risk of the roots being dried too much. Another source of great injury to plants in the borders is their roots getting in contact with the walls which divide the beds from the hot-water pipes where they are so arranged. Keeping these parts well moistened prevents part of the injury, but in cases of this sort the beds or borders ought to be protected by a few inches of some non-conducting material, as dry sawdust or pounded charcoal, cased with a brick-on-edge wall between it and the soil. This arrangement ought never to be omitted where the pipes run under the paths, &c.—*D. B.*

II.—FLOWER-GARDEN AND SHRUBBERIES.

Out-door Department.

This has been a very favourable season for the blooming of out-door Chrysanthemums, and I do not recollect to have ever before seen them in such fine condition, or to so much advantage. For the autumn decoration of the flower-gardens, especially in country places, they are certainly deserving of more attention than has hitherto been bestowed upon them; and for that reason I have, through the kindness of the Messrs. Chandler, who favoured me with specimens of their newest flowers, made an arrangement (represented by the figures below), in which some of the finest kinds in cultivation are grouped according to their complementary, or rather contrasting colours. The figures may be considered either to represent separate groups, or single plants in a large bed. Whichever arrangement is adopted, it is necessary that the plants should not exceed 18 inches in height, and for that reason they ought to be layered in July in the reserve garden, and be removed to their flowering quarters in October:—

1	2	3	4	5	6	7	8	9
10	11	12	13	14	15	16	17	18
19	20	21	22	23	24	25	26	27
28	29	30	31	32	33	34	35	36
37	38	39	40	41	42	43	44	45

1 Isolier	16 Aristides	32 Marie
2 Golden Lotus,	17 Vesta	33 Compactum
flowered	18 Julius Cæsar	34 Comte d'Eu
3 Imogene	19 Park's small Yel-	35 Elegans
4 Casimir Perrier	low	36 Duc de Cornegli-
5 Gouvion St. Cyr	20 General Lamoricière	ano
6 Horatio	21 Horatio	37 Phidias
7 Madame Pompa-	22 Connector	38 Distance
dour	23 Louis-Philippe	39 De Crequi
8 Demarce	24 Marshal Soult	40 Annie Jane
9 Surprise	25 Campestrom	41 Queen of Yel-
10 Grand Napoleon	26 Empress	lows
11 Lac dum	27 David	42 Leontine
12 Incomparab'e	28 Julius Cæsar	43 Arago
13 Celestial	29 Minerva	44 Formosum
14 Sappho	30 Queen of Gipsies	45 Flechier
15 Rigou	31 Phidias	

The preceding arrangement would, I am certain, produce a fine effect in the autumn, and would amply compensate the culturist for any care he might bestow upon the preparation of the plants.—*W. P. A.*

III.—FLORISTS' FLOWERS

Should the weather continue fine, much can be done amongst Florists' Flowers; still there are always full employment even in unpropitious weather like the present. We last week stated that Carnation compost or loam, as the case may be, should be frequently turned; when the outside of the heap is frozen it may be removed, so that a fresher layer of soil may be exposed to the action of the frost; and should the hard weather continue, this in like manner may be removed, and each successive crust taken away till the whole heap has been frozen. This has a highly beneficial effect on the soil, and is the means of destroying the eggs and larvæ of many injurious insects. Leaden Carnation pegs may now be straightened, cleansed by washing, and put by till the next layering season; fresh ones may also be procured. Carnation sticks should be repainted, and, in fact, all such matters must be attended to. As for layers in pots, the less they are meddled with during severe frost the better; where they have been potted off early, and are well established, they will endure severe cold without injury, and may have all the air possible; on the other hand, if they have only been put in during November, the frames must be kept rather close, only giving air during the middle of the day. *Auriculas.*—When healthy will bear frost with impunity. The frame-lights may be tilted during the middle of the day. We have known the soil in Auricula pots to be frozen as hard as marble without any apparent injurious effect on the plants. *Ranunculuses.*—May occasionally be looked over, taking care to keep them in a moderately dry place; if not previously done, the roots may be cleaned and made ready for planting. The beds will be benefited by being turned during the frosty weather, but as Ranunculuses do better on beds of a close texture, it will be as well not to remove the soil after the end of the month; merely throw it up in ridges of about 3 or 4 inches, it will thus be exposed to the action of the weather, and may remain so till planting time, when all that need be done will be to rake the beds level, previous to putting the roots in the ground. *Pansies* —Are kept by many in pots during winter; when well established they will bear a great degree of frost. It would be advisable, however, where the collection is of importance, to hoop the beds, over which mats may be thrown.—*J. F. W.*

IV.—PINERIES, VINERIES, &c.

Pineries.—During the continuance of severe frost, the temperature of the fruiting-pit must not exceed 60° by night. The other *Pines* may also be kept a few degrees lower than in mild weather without injury, if not with benefit. The fires necessary to maintain a high temperature during severe frost, are always more or less injurious to the plants, as a corresponding degree of moisture cannot be artificially maintained. Examine frequently, the plants near the pipes or flues, and supply water to any that may require it.

Vineries.—The best time to start Vines for an early crop has often been discussed, and some attempts have been made to have ripe Grapes in March, by beginning to force in September or October. This, however, is not often done, November being the time when most gardeners begin to force their first houses. From my own experience, I am led to believe there is no difficulty in getting Grapes early in March, even from Vines having their roots outside the house; and I will shortly give my reasons for so thinking, and my mode of practice. Vines to be started between this time and Christmas should now have their roots covered with leaves and stable litter, so as to create a gentle heat in the border, in order to put the roots in advance of the branches. Continue to keep the night temperature of the vinery started in November at 50°, if the buds have not begun to swell generally, and sprinkle frequently the Vines and the floor of the house. Vines now breaking keep between 50° and 55° by night, and 60° by day.

Peach-house.—Continue to keep the night temperature at 50°, with a day temperature of 55°, allowing a rise of 10° or 15° with sun-heat. As soon as the blossoms begin to expand, let a small portion of air be left on during the whole day, making up the deficiency of temperature by fire-heat, if necessary. This is requisite to give strength to the blossoms. Sprinkle the trees frequently, until they are in bloom, after which only sprinkle the floor and paths until the fruit is set.

Cherry-house.—This house may now be shut up, and kept at a temperature of 45° with fire-heat. Cherry-trees are easily excited; great caution should therefore be used not to keep them too warm. Giving air is not necessary, except during sunshine, until the buds begin to expand, when it must be admitted at all favourable opportunities. Plunge trees in pots in slightly-fermenting material.—*G. F.*

V.—HARDY FRUIT AND KITCHEN-GARDEN.

The latter end of last week, and the commencement of the present, would witness abundance of protecting operations. Fortunate were those who had everything in readiness for the work, for, though we had a warning of keen north-easterly winds for some time, yet 12 or 16 degrees of frost has of late been so uncommon in the beginning of December, that many of us are too apt to procrastinate, and say "It is time enough yet." All the more tender vegetables, such as Cauliflower, Lettuce, &c., previously secured, will now be found of great service during the winter. The possession of rooms, or sheds, with thick walls, and lathed and plastered so as to be cool in summer, and warm in winter, or access to cellars, or underground rooms, will be of great advantage, as then a supply may be maintained with comparatively little trouble, during either severe weather in winter, or for a month or two of dry scorching weather in summer. The north side of a wall, with material to keep out the wet, and leaves or straw, to keep out the frost, may also be used with advantage. The passages of an old-fashioned ice-house, to which access is requisite several days in the week, may also be used as a substitute for cellars, &c. I tasted some Cauliflowers the other day, crisp, and fine-flavoured, that had been so kept for more than two months. *Store-house.*—Secure Potatoes from frost; examine Onions, removing every one that has the smallest speck; keep a supply of Turnips, Celery, Jerusalem Artichokes, Horse-radish, &c., in case the frost should be apt to continue. *Fruit-room.*—Keep the temperature as regular as possible, ranging from 35° to 45°; if allowed to rise higher, the fruit will ripen too fast; and if the fruit is frosted, the flavour will be apt to be injured, besides being liable to rot, if it should be thawed suddenly. When it is desirable to render any sort fit for table, it may easily be done by exposing it to a higher temperature, and thus accelerating the saccharine fermentation. *Forwarding.*—Keep up a supply of herbs, such as Tarragon, Mint, &c., by placing roots either in pots or in Asparagus-frames at work. The same thing may be done with Parsley, Chervil, &c., if you are likely to be short. Fill pots or boxes with Rhubarb, Sea-kale, Chicory, &c., to be placed in the Mushroom-house, or in any corner where you can have heat and darkness at command. Those who have commenced Cucumbers, or have some in a bearing state, will find considerable attention necessary, where there is nothing but fermenting material to depend on.

Routine.—Wheel dung upon vacant ground; remove old decayed borders, and drive good fresh loam to form new ones. Mulch all fresh-planted fruit-trees; protect the tops of those the wood of which is not properly ripened, with Fir-branches, Fern, &c. Clean old shreds not too much wasted for use, by boiling them, and cut plenty of fresh ones. Deprive nails that have been used, of the adhesive mortar, &c., by heating them red hot in an iron vessel; and to prevent them from rusting, immerse them in oil before they cool. Anoint all trees and bushes that are pruned with a mixture of equal parts of cow-dung, clay, soot, and lime, made to the consistence of paint, with strong soapsuds, urine, or the rich drainings of the dung-hill; and if you prune at all in such weather; let the wounds be immediately daubed up with a thick composition of the same.—*R. F.*

VI.—ARBORICULTURE.

Old Woods.—As the weather has set in frosty, continue to fell trees, and clear them away. Cut hedges, and forward any other work which can be done in frosty weather.

Coppice.—The cutting of poles and other produce might be forwarded, where there is much to do in that way; but February, March, and April is the best season for such work.

Young Plantations.—Where there is much thinning to be done, such weather as we now have is excellent for cutting out Larches, &c.; but such plants as are required to spring up again, for underwood, to be headed off, should be left till the spring months.

Hedge-rows.—Planting and cutting these may be proceeded with.

Nursery Work.—Little can be done now in this department while the frost lasts. Secure the plants from hares and rabbits, if previously omitted, and shelter tender plants from the severity of the weather.—*W. B.*

VII.—COTTAGERS' GARDENS.

Pelargoniums that were cut down, dibbeted, and repotted in fresh soil early in autumn, should now, if they have been well treated, be handsome plants, and should be carefully protected from frost. In weather like the present, these, as well as other plants, should be drawn back from the window, or set down on the floor of the room. Water very sparingly while the frost continues, and even in mild weather no more water ought to be given to plants in windows in winter than just enough to keep *all* the soil in the pots sufficiently moist to maintain the plants in a healthy state. Cauliflower-plants, if any, growing under a south wall, will be greatly benefited by straw, Spruce Fir-branches, or some other material being laid over them, partly with a view to keep off the severe frost, and partly for the purpose of preventing the plants from being suddenly thawed by sun-heat in the middle of the day. To plant that is at all tender will almost being subjected alternately to hard frost at night and moderately high temperature during the day, which is generally the case with plants that are unprotected in such a situation. Now that the ground is hard frozen, and nothing for the cottager to do in the way of digging, I shall feel greatly obliged to any one who will send an article to the *Gardeners' Chronicle* on the best method of protecting the tender plants in cottagers' gardens, against the severity of the weather.—*T. Hall.*

Abstract of the Weather near London during the week ending December 7th, 1844, as observed at the Horticultural Gardens, Chiswick.

Day of Month	Day of Week	Barometer		Thermometer				Rain in inches
		Max.	Min.	Max.	Min.	Mean	Dew point	
1	Sun.	29.816	29.606	50	34	42	38	
2	Mon.	29.806	29.564	54	30	42	38	
3	Tues.	29.772	29.676	52	32	42	38	
4	Wed.	29.719	29.597	52	32	42	38	
5	Thurs.	29.704	29.605	52	32	42	38	
6	Fri.	29.668	29.547	52	32	42	38	
7	Sat.	29.664	29.580	52	32	42	38	
Average		29.718	29.657	51.7	31.6	41.7	38	

Sun—Cloudy; frosty and foggy; clear; fine; severe frost at night.
Mon—Cloudy; frosty and foggy; overcast; cold; brisk N.E. wind; cloudy and frosty.
Tues—Cloudy; frosty; overcast; cold; brisk N.E. wind; cloudy and frosty.
Wed—Cloudy; frosty; overcast; dark and cold; gloomy; frosty; overcast.
Thurs—Cloudy; frosty; overcast; dusky haze; clear; hard frosty.
Fri—Cloudy; frosty; overcast; rather boisterous at night.
Sat—Cloudy; frosty; overcast; cold; rain at night.

The temperature of the week 15 deg. below the average.

Statement of the Weather at Chiswick during the last 18 years, for the ensuing Week ending Dec. 21, 1844.

Day of Month	Day of Week	Aver. Highest Temp.	Aver. Lowest Temp.	Mean Temp	No. of Years in which it Rained.	Greatest quantity of Rain.	Prevailing Winds.							
							N.	N.E.	E.	S.E.	S.	S.W.	W.	N.W.
Sun.	15	46.2	35.6	41.0	8	0.35 in.	1	2	—	3	6	4	2	—
Mon.	16	46.6	35.6	40.7	12	0.45	—	2	1	2	3	3	5	4
Tues.	17	46.6	35.2	40.9	10	0.37	2	1	—	2	2	6	3	1
Wed.	18	45.8	35.3	40.6	5	0.80	2	6	—	1	2	3	5	—
Thur.	19	45.5	37.0	41.2	6	0.88	1	3	1	1	3	6	3	—
Fri.	20	45.2	35.5	40.3	7	0.70	—	4	—	2	3	7	1	1
Sat.	21	46.0	36.2	40.6	5	0.80	—	3	1	2	2	6	2	2

The highest temperature during the above period occurred on the 17th 1833—therm. 57°; and the lowest on the 18th, 1841—therm. 16°.

Notices to Correspondents.

The Reprint of Mr. PAXTON'S COTTAGERS' CALENDAR is now ready, price 3*d.* each Copy. An Index has been added to this present Edition. Parties wishing to have copies for distribution among their tenantry can have them at the rate of 2*s* for 5*s*.

Apples.—*G.*—The Waltham Abbey Seedling is a good kitchen Apple, requiring very little sugar. You will probably find it, when cooked, much superior to the very sweet Apples you mention.‖

Asphalte.—*G. R.*—This substance has not been used in the gardens of the Horticultural Society for the roofs of buildings. It has only been employed for small boxes to guard plants in the open air from cold, and to cover borders for experimental purposes; for this it answers very well. We are unacquainted with the other. Your commission shall be attended to.

Books.—*A. B.*—"Glendinning on the Pine-apple," and "Hamilton on the Pine-apple." Both should be in the hands of all gardeners.

Camellias.—*Amateur.*—Certainly Camellias will grow against a brick wall with an east aspect, in a border of fresh sandy loam, leaf-mould, and peat, 3 feet broad and 1 foot deep, with 9 inches of broken bricks and gravel below, upon a dry bottom, if you cover them during winter with sashes and mats when necessary, although you are in a rather cool and moist climate. Plant them 6 feet apart; if they like the soil, they will soon meet. It will be as well, however, to enrich your soil with a good dressing of manure. Experiments show that guano and urine furnish a most efficient liquid manure for these plants. Keep their stems pretty close to the wall, but suffer the branches to grow bushy. The mat covering will not be important, unless the weather is very severe, and not even then, if your sashes are tight, and the border thoroughly drained. As to Mangoes, they most certainly will not bear the treatment of the Peach. It is folly to think of it.

Carnations.—*G.*—The "black spot" on the leaves of Carnations is infectious, propagating itself in the same manner as *rust* in corn, or mildew on plants. If you will submit them to a powerful microscope you will find that they are composed of innumerable small *fungi*. We should imagine that the spots on the leaves of Polyanthuses (though we have never submitted them to the same test) are of a similar nature.—*W.*

Celery.—*An Inquirer* solicits information from some of the successful competitors at the Uxbridge Show as to their manner of managing to obtain such fine heads.

Covering for Frames.—*J. G. Reading.*—The following is the mode of preparing the composition described by "Devoniensis," at pp. 301, 1843; and 302, 1844, viz., "Three pints of old pale linseed oil, 1 ounce of sugar of lead, and 4 ounces of white resin. The sugar of lead must be ground with a small quantity of the oil and added to the remainder, incorporated with the resin by means of gentle heat. The composition is to be laid on by a brush, after the calico is nailed to the frames. One coat annually is sufficient. It dries in a short time when exposed to the air; and excludes as little light and heat as anything except glass, and does not become mildewed."

French Beans.—*An Old Subscriber.*—The Early Dwarf Dutch Haricot is one of the very best for forcing.‖

Game.—*J. M.*—We are sorry to hear that your plantations are destroyed by hares and rabbits; and we are still more sorry to be unable to help you to a remedy. Shoot, snare, trap, and poison, we should say, if you dare; but as we presume you have no taste for transportation, we do not advise you to practise such devices. The truth is, that until the Game-laws are wholly repealed, poor people must submit to have their property destroyed for the gratification of the rich.

Gold Fish.—*W. Ellis.*—The trout is a fish of prey, and consequently would devour small Gold-fish. The best time to put Gold-fish (that have been kept in a glass globe in the house) into a pond will be the spring, say the end of April, or beginning of May, and not in the autumn. The Strawberries can be had of all nurserymen.

Heaths.—*W. T. O.*—The following varieties, if treated in the usual way, will flower between the months of November and May, viz., Verticillata, Mammosa, M. pallida, Hyemalis, Willmorcana, Vesecitii, Grandiflora, Arbuscula, Umbellata, Lamberti, L. rosea, Versaia, discolor, Acuminata, Perspicua fabre, P. alba, Pyramidalis, transparens, and Regerminans. In the case of the plants exhibiting a disposition to bloom early in summer, the strongest of the shoots should be stopped, which will make the plants flower more profusely in autumn and winter. Heaths are not fond of manure. The finest of flower-pots vary in different parts of the country; a No. 16 near London measures 11½ inches in diameter at top and 10 inches in depth.‡

Hints.—*C. N.*—We should not have thought it possible that your house would be too damp. If it is so, you may diminish the porosity of your tiles by a coat of Roman cement. That would be the cheapest plan, and effectual.——*A. B. J.* says that in "Loudon's Encyclopædia of Gardening," p. 890, in a paragraph respecting the tempering of brick flues with "linseed putty," he inquires, what is meant by "lime putty," and how it is made.

Hoeing.—*A. B.*—You are not too much for the wisest of young shelves, but that is a point of little consequence, and merely depends upon the fancy or objects of the owner, who constructs a greenhouse. It is of far more importance to construct a double shelves of wooden rails. By all means, if you can, construct plate shelves. The pipes may be placed between the rails and the shelves, but that is not of much consequence if you keep them, the latter. Double walls keep the plants over solid walls of brick-rubbish chamber, and much drier and warmer. Nine inches are enough for the side shelves. Determine the size of the panes of glass by the size of your house.

Hyacinths.—*M.*—The leaves of your plants have probably been punctured earlier in the year by the Thrips or some other insect, but the species cannot be determined, as there are no specimens to be found upon them.—*R.*

Ivy.—*Philo-Rosa.*—This plant does not derive much nourishment from the roots by which it is attached to walls; by no means enough to render the branches independent of the roots in the earth. If you want to cut a window through a mass of it, you must do so by carefully putting it aside—not by cutting through the main branches.

Lesson in Nature.—*A. W. B.*—Your treatment has been judicious. These plants do not require stove temperature, nor do they like it. Full details of their management would occupy more space than we can afford them at this late period of the year. As soon as the next Volume commences we shall give *full practical directions for* the management of all such things.

Manures.—*Mansilow.*—Certainly, if you have no tank to hold the chamber-ley, pour it upon your beds; that is better than letting it run to waste. But it is a bad way of applying it. Cannot you get an old wine hogshead or something of that sort, and when it smells throw in some sulphate of iron? You may depend upon it this sort of manure, well managed, is among the best, if not the best of all.

Mistletoe.—*W. H.*—The Mistletoe is found in this country upon the Lime, Maple, Apple, Oak, Willow, and Poplar. In Germany it grows in great quantities upon the common Pine. It may be cultivated by making an incision in the bark of the tree on which it is to grow, and inserting a berry or two; then tying a little damp Moss over the part. The operation may be performed in April or May; the berries like to be kept rather moist until they begin to grow.‡

Names of Fruits.—*T. H. T.*—1, Beurré Diel; 2, Crassane; 3, Glout Morceau; 4, Chaumontel; 5, Passe Colmar; 6, Beurré Dalu; 7, Marie Louise; 8, Brown Beurré; 9, Chaptal; 11, Easter Beurré; 12, Bishop's Thumb; 13, Blenheim Pippin.‖——*Mickle.*—Nos. 1 to 6 inclusive, correct; 7, Scarlet Nonpareil; 10, London Pippin; 11, Royal Russet; 12, Northern Greening.‖——*A Subscriber.*—Your Pear is not the Van Mons Léon le Clerc.‖

Names of Plants.—*D. N., Cork.*—Maxillaria picta.——*M. R. L.*—Acacia lophantha.——*Alpha.*—1. Vicia lutea; 2. Anemone ranunculoides; 3. Chamædeon procumbens; 4. Campanula; 5. Trifolium elegans; 7. Smilacina bifolia; 8. Erigeron acris; 9. Myosotis arvensis; 10. Trifolium incarnatum.‖——*R.*—Apparently Oncidium Sutoni.

Pines.—*Reformer.*—Your questions should be addressed to the nearest bookseller. Such inquiries as you have made cannot be answered without subjecting the answer to advertisement duty.

Root-pruning.—*An Old Subscriber.*—If the roots of young trees can be properly spread out it is not necessary to prune them, in planting, if they are sound; and all that is unsound should of course be cut clean off.‖

Roses.—*S. Warnford.*—The following are handsome, and are suitable for being planted out singly on a lawn, viz.:—Lamarque, Madame Desprez, Brennus, Félicité Perpétuelle, Blairii, Billiard, Amadis, and De Lisle.‡

Stables.—*Rigata.*—We will give you an answer next week. It is certainly desirable that a loft or chamber of some kind should be constructed over a stable.

Strawberries.—*John.*—Some kinds of Strawberries originally obtained from North America, and varieties subsequently raised from them, are so hardy that out most severe winters do not materially injure them. But the Chili Strawberry is rather tender, a characteristic which the numerous cross-bred varieties from it more or less inherit. Myatt's British Queen, and some other new kinds, though not perhaps directly cross-bred, yet appear to have something of the Chili in their constitution, and therefore you will do well in covering those you planted in August with litter, or leaves, or with a mixture of both.‖

Timber.—*Clithero.*—The plan of barking trees while standing, and leaving them till another year before felling them, has long been practised, but it seems out of favour. Boucherie's mode of injecting trees is only applicable to them when freshly cut or growing. His mode of proceeding has been described at p. 911 of the Volume for 1843.

Transmutation of Corn.—We learn from a correspondent that the statement in an Irish newspaper about Oats having been found growing on an ear of Wheat originated in error.

Transparent Coverings.—*X. E. L.*—The turpentine should not be boiled with the oil, but stirred into it when taken off the fire. The oil is raw linseed-oil.‡

Window Flowers.—*J. H. G.*—All common greenhouse plants, with the exception of Heaths and shrubs of that description, will grow in windows, provided they are properly managed. The easiest to grow are what gardeners call soft-wooded, such as Geraniums, Fuchsias, and Aloysias; or herbaceous plants, like Chinese Primroses; or succulents, among which Echeverias and some of the Crassulas, especially *C. coccinea* and *versicolor* are the best; or, finally, the common bulbs and corms called in the shops Dutch roots. The difficulties to contend with in a sitting-room are darkness and dryness of the air; the former interferes with blooming, the latter with growing. The former is only to be remedied by turning the whole window-garden out of doors for a few weeks every year; the latter by the use of bell-glasses, at night, or similar contrivances. The common errors to avoid are insufficient drainage, a most important point; watering with cold water, and allowing water to stand in the pans that receive the pots. In the early part of next year we shall furnish a series of articles on these matters, till when we must solicit your patience. For outside creepers, take Honeysuckles, Glycine sinensis, White Jasmine, and the Sweet Virgin's Bower.

Miscellaneous.—*F. M.*—Triptilion spinosum is a pretty plant enough, but very hard to grow. We doubt whether it can be had in the trade. It may be kept in a cold frame, but it requires a very abundant ventilation, and is best in a greenhouse.——*A. W. B.*—Caffre Corn is the grain of Sorghum saccharatum and some other species. It is too tender for cultivation in this country. The Hottentots are very fond of sucking the sugary straw. The common Passion-flower often ripens its fruit near London. We never heard of its seedlings being better than the parent, and should doubt it. Your information delights us.——*J. C. S. B.*—Neither you nor any one else can raise Rhododendrons true from seed, unless you take the precaution of *setting* them when in flower. If you sell them all but the ponticum nobody can complain.——*A. H. G.*—You can have all the Numbers for this year, price 1*s*.——*Tamarisk.*—The arrangement of plants in a garden, according to their botanical system, is possible; but incompatible with ornamental effect. For this reason it is not found in gardens. At the Horticultural Society's Garden the plants are usually labelled with their names and native countries.

R. E.'s is alive and well; he is not the personage to be alarmed by silly and ignorant people; but he has been too much engaged to find leisure for us. With the turn of the year his contributions will be resumed. Your question pondering queries is very difficult to answer, for it involves some of the most obscure phenomena of vegetation. It is probable that we shall touch upon it in a few weeks. As to the other matter, it is, we fear, irremediable.——*D. P.*—Cabul being a large city several varieties of Melon are sent from there, which are all termed Cabul Melons. The name is not applied to any particular sort, consequently both your green-fleshed and scarlet-fleshed varieties may be equally Cabul Melons.‡——Received, *T. T.*

* * As usual, many communications have been received too late, and others are unavoidably detained till the requisite inquiries can be made.

DRAINING OF LAND.—THE WORKMAN'S LEVEL, invented by Mr. BAILEY DENTON, is made and sold, as approved by him, by Messrs. Jones, Opticians, 30, Lower Holborn, London, price 30s.

The Agricultural Gazette.

SATURDAY, DECEMBER 14, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.

We refer our readers to the Report, in another column, of the SMITHFIELD CLUB SHOW OF FAT CATTLE, &c., which has taken place during the past week. We shall have a few remarks to make next week upon the relative and actual importance of that branch of farming which this Society takes under its patronage. In the mean time, we have only to observe that the animals shown were in no respect inferior to those exhibited last year; and, what is of importance to the exhibitors, the weather has been such, that the butchers have not been afraid to give full prices for what has been sold.

LET us now apply to the systems under discussion—those of PERMANENT PASTURE and ARABLE CULTURE—the tests, the accuracy of which we last week justified. How do pasture lands fulfil the required conditions? Do they yield much profit to the occupier? Are they largely productive of food for man? Do they give much employment to the labourer? The very *best* pasture lands—lands naturally fertile, and upon which Grass is a natural crop, and is, therefore, produced in abundance—answer the first and second questions satisfactorily. They afford a good profit to the owner and occupier, and produce a fair amount of food, in the shape of beef and mutton, for the public. The third condition, however, is totally neglected; they provide scarcely any labour. The labourer's share is, in fact, absorbed by the owner, and that without gain to *him*. For instance, upon soil of this sort the rent is never less than half the gross produce. The same soil under the plough pays only one-fourth its gross produce; though ordinarily the *amount* of rent is the same in each case. If labour were employed in the former case, as in the latter, rent would necessarily suffer a reduction. It is obvious, therefore, that the former system yields too little produce, as the rent is the same in amount, in both cases, and that its produce is divided between the *owner and occupier only*, instead of admitting the labourer to a share. To admit him to a share without diminishing that of the owner and farmer, a system must be adopted which produces *more*. Whether this can be done or not, however, he is entitled to his proportion, and in this system it is forgotten.

If we apply the same test to the medium and inferior Grass lands—in fact, to three-fourths of the pastures of the country, the demerits of the system are fully developed. The profit upon them in the shape of rent is small, and the interest to the occupier, except in the shape of convenience or accommodation, is in most cases insignificant; in many it is on the wrong side of the book. The gross produce of such land, in the shape of flesh, is on the same scale as the profit—*i.e.* of course, it does not supply. Indeed, there is a great proportion of our inferior pastures which will not *feed* anything. Upon these young stock *exist*, and the progress of age is in some degree attended by growth; the stock, therefore, in time acquires an increased marketable value. In amount, however, this is trifling, and would be were it not that such lands are but *parts* of a farm, and are in some cases let for convenience, and make part of a better bargain) afford a rent very much less than they now pay.

On these soils, however, the labourer is entirely forgotten. Producing so small an amount of food for the country—*little* for the owner, and *less* for the occupier—there is *nothing* for the workman. For the amount of employment on this Grass is not worth naming. On each point, then, in which it is essential that a system of management should excel, this fails. A method which affords little for anybody, and nothing for some who ought to receive advantage from it, cannot be acceptable to any interest, or worthy of being practised by any enlightened cultivator.

The question is, however, now, How would the arable system answer in these cases?

To plough out these soils, say many spirited and intelligent advocates of the arable system, would do all that we require; would protect the two interests which, under the other system, suffer most—the country and the labourer—without injury to the interest of the owner and cultivator.

Investigation bears out this statement. Even on the good pastures, to which we in the first instance referred, the arable system would produce to the labourer at least a quadruple supply of *employment*, and to the country a doubled amount of *produce*. For two excellent artificial green crops, and two grain crops, would undoubtedly be twice the value of four crops of Grass to be depastured. *The profit*, therefore, would surely not be diminished, as there would be one-half of the produce to pay the labourer and other expenses, and still as much left for rent and profit as was produced altogether under the pasture system. This is evidenced by the fact already noted, that a similar rent for land under the plough and under pasture, is at least calculated at respectively one-fourth, and half the produce. It is clear, therefore, that the produce is in one case double what it is in the other, and that one half of it is paid away in the *extra labour*, &c., and still the rent and profit is as great upon the arable as upon the Grass land.

If these advantages accrue in adopting the system upon even *good pasture land*, how much more strongly must they be felt upon the ordinary and inferior soils, where, in many cases, sterility is the natural condition? To such poor or unimproved soils rich herbage is not natural: they will not, therefore, voluntarily produce it. But by cultivation, tillage, and manure, they may be made to produce artificial crops, however inferior their natural one was, and consequently they will, under such a system, afford in a higher degree than when under Grass, all the essentials we require—viz. *profit*, *produce*, and *labour*. In illustration of this, on a moderate estimate we may, on that half of the Grass which on the alternate system would be under Turnips and Clover seeds, keep quite as much stock as the whole in bad Grass would keep. The country would suffer no loss of *mutton* from the change. We should, in addition, have the other half in corn, and this would be so much clear *gain to the country*, and would be equal in value to at least three times the former produce of the whole in Grass.

The gain to the labourer, and the profit to the farmer, &c., are also evident. With the same permanent burthens (rent, taxes, &c.) to bear, and a produce quadrupled, there is (taking the value of the old pasture for these burthens) three times the whole produce if under Grass, to pay the interest of capital with, to employ the labourer, and to spend in manures and in other matters requiring the capital and industry of the country.

Upon these grounds, then, it will be evident that the conditions which we consider essential, in order that a system of cultivation may be beneficial to *all the interests* vested in the soil, are more fully answered by the arable than the pasture method. We have no hesitation in affirming, therefore, the truth of the position which has been publicly propounded, that the interests of the community require that the change from the pasture to the arable method of cultivation should be extensively adopted on the medium and inferior lands of the country. We say medium and inferior lands, because they are far the greater proportion of the pasture lands of England; and it is on them that the greatest and most striking benefit would arise from the change of system. Moreover, the best Grass lands are principally held in small quantities, and along with other qualities of land; they are, therefore, matters of great convenience to the farmer, allowing him to keep more cattle in his yards during winter, to consume his straw and improve the quality of the manure, as he can feed them off in summer on this good Grass land. Although, therefore, by ploughing out such land we might obtain a greater annual produce, and perhaps more profit, yet, paying as they do a fair interest and affording accommodation in so many instances, it can scarcely be expected that these lands will be ploughed out solely because they do not afford labour. Nor indeed can we wish for the change while the medium and poor Grass lands exist in such quantity, and promise so much more beneficial results. In *them* the change is from *nothingness*, both as regards *occupier's profit*, *gross produce*, and *labour*, to a fair proportion of each. And from being a burthen (for such we maintain they are to many farmers who taking them in their farms, are not aware what they pay for them, and are almost as ignorant of what they get from them) they become a source of wealth to the country, and a means of ministering comfort to our fellow beings.

The case, indeed, is simply this:—We can grow good crops, by artificial means, in soils which of themselves will grow little. Are we to compel these soils to be useful or not? We can in fact, increase the value of the crop tenfold, and at the same time quadruple the amount of employment, and consequently the amount of payment to the labourer. The question, therefore, is—Is it good policy to do this at a time when both are objects of the greatest national importance?

As it may undoubtedly be urged that the increase of produce and employment, to the extent we have claimed, from the conversion of pasture into arable land, is an assumption, we shall in a future Paper prove that facts support our assertions.—*H.*

INCLOSURES FROM THE FRITH OF TAY.

"What is the best mode of bringing mud from the sea into cultivation?" In answer to this query I beg to say that the remarks I intend to make will have reference solely to the river Tay, and of course may not be applicable in all cases, as which depends upon the nature of the river, its currents, &c., and the geological formation through which it flows; so that the alluvial deposit of one river may differ from that of another.

The subject may be divided into three divisions, and a few remarks on each made.

1st. The method of gaining land from the river.

2d. The method of protecting it when gained.

3d. The mode of cultivating it.

1st. As to the method of gaining land from the river. The process usually followed with the most advantage is to run out at intervals double rows of stakes, driven five or six feet into the ground, leaving their tops three or four feet above it, two or three feet apart from each other, then firmly filling the space between with twigs, branches of trees, or tops of hedges, calculated to catch the particles of mud but to allow the water to pass through. A sediment thus takes place between the rows, and gradually increases, and ultimately forms a firm productive surface; care must be taken to prevent all ditches or running streams from passing through it, as they would prevent it from mudding up. Sometimes a row of loose stones is laid between the current and the deposit, or between high and low water mark, which will similarly catch mud and sand, and while forming new land will, by narrowing the channel, give greater impetus to the stream, and help to deepen its bed; but lately, since the dredging or deepening of the bed of the Tay, proprietors have availed themselves of the sand and gravel excavated from the bottom of the river in forming fine sloping beaches, thereby saving the expense of loose stones. Sir John Richardson, of Pitfour, in particular, has now a fine hard sloping beach of about two miles in extent, along the extremity of about 100 acres in process of mudding up.

2d. As to the method of protecting it when gained. This is done by raising a large earthen mound parallel to the shore. The two sides of such a mound are generally formed on different slopes; that towards the land is always the most abrupt, but can never be secure if more than at an angle of 45°; that towards the water varies from 45° to 25°; of course the greater the slope the better, but as a general rule it should never be less than two feet to every foot in height—the power of the bank to resist the weight of the water, as well as to break its force when in motion, being inversely as its steepness. Some of the banks are formed with a stone wall half their height next the water, with a long slope, and then a mound of earth at the back and over it; but the earth alone is the most general mode, and seems better adapted than the other. Mr. Stephens says, "An embankment was thrown round the small island of Mugdrum in the river Tay, to protect the land from being overflowed by the tide, but it was made so steep that the first spring tides levelled the greater part of it to the ground; a second attempt was made, with the additional expense of a stone wall facing the water, which shared the same fate with the former bank. Since these failures, a third embankment has been erected, with nothing but the natural soil of the land, and the whole covered with thin turf: the length of the present slope next the sea is five times the perpendicular height of the bank, and the inner slope three times; the water meeting no resistance rolls down the long slope without doing any injury." Sluices or tunnels of boards, with a valve opening outwards on their exterior extremity, are introduced here and there through the bank dyke, to carry off the water within; when the flow water from without approaches, it shuts the valve, which remains in this state till the tide recedes, when the height of the water within being greater than that without, it presses open the valve and escapes.

3d. As to the mode of cultivating it. This does not seem to be a very difficult process, as the soil, if not taken in too soon, is comparatively dry, and naturally a very fertile one. In 1826, about 80 acres were taken in on the estate of Pitfour. The first year it was trenched to the depth of 18 inches, the surface or the undecayed vegetable matter thrown into the bottom of the trench, then sown to Oats, next Potatoes, then Wheat, and, with the exception of occasionally Clover, Oats, and Beans, has been Potatoes and Wheat, alternately, ever since; in fact, this, generally speaking, is the mode of cropping followed, Potatoes and Wheat being held as staple articles. On a neighbouring estate, about 60 acres were taken in two years ago: after allowing it to dry so as to carry the horses, it was ploughed, then levelled with a levelling box, and Oats sown the first year, then planted with Potatoes, the crop of which averaged somewhere about 20 tons per Scotch acre. Perthshire has for a long time grown large quantities of Potatoes for the London market, and these alluvial or haugh lands, as they are locally termed, are first-rate Potato-growing soils. The average rent of such soils may be from 4*l.* to 5*l.* per acre, or an equivalent in grain.—*A Strathearn Farmer.*

THE PLOUGH.

(*Continued from p. 816.*)

We have now to consider the second question we proposed—What form of the plough will effect its par-

pass with the least exertion of power? It is only the mould-board which is here referred to—the cutting parts of the plough, to the action of which much, perhaps most, of its draught is owing, have been already considered. I am persuaded that the theoretical consideration of this question is of little utility. I believe that the form of mould-board of least resistance will be sufficiently nearly pointed out by experiment. The question is, however, an interesting one, and that perhaps chiefly on account of its great complexity. It appears that in ordinary cases, and more especially in ploughing turf, the friction of the sod upon the mould-board is due to the action of two causes. One of these is the weight of the sod, and the other is its resistance to being bent—its elasticity. Let us divide the mould-board of the plough into two parts:—first, the front part, which is employed in raising the turf from the horizontal to the vertical position; and secondly, the hinder portion, which is employed in pressing the turf from the vertical to its ultimate position. A little consideration will show that in the former of these portions both of the above causes act, while in the latter only one of them acts. In the former, both the weight of the sod on the mould-board, and the resistance it offers to being twisted, concur in pressing on the mould-board, and thereby producing friction; in the latter the sod, so far from lying on the mould-board, tends to fall away from it; its elasticity alone remains to produce friction. It is evident that the twist of a sod will be most easily effected if done gradually. If the elasticity of a turf were all that was to be overcome, this would be more easily effected by laying hold of it at a distance of four feet from where it was attached to the fast land, than if it were held and forcibly bent at a distance of only two feet from the same spot: obviously, if the elasticity of the turf only were to be overcome, the longer the mould-board the more easily it would act. If we now look at the influence of the mere weight of the sod in producing friction, and thus adding to the draught of the plough, we shall find that the shorter the mould-board the more easily it would act; for the longer the mould-board, the greater would be the weight of turf lying on it, and, consequently, the greater the friction due to that weight. The inference from the results at which we have thus arrived is, that the hinder part of the plough, on which only the elasticity of the turf acts, should be as long as is consistant with convenience, and that the length of the front part of the mould-board should be such that the sum of the two portions of the friction on it—the one due to the weight, and the other to the elasticity of the turf—may be a minimum. With reference to the front part of the mould-board it thus appears that the proper dimension lies somewhere between the shortness, which is in accordance with the one view, and the length, which is in accordance with the other; in which, each kind of force being taken into consideration, the sum of the forces required to overcome each is a minimum. It is the length of the front part of the mould-board that forms the great difficulty of the question; for consideration must be kept alive to the fact, that as it varies, one of the above portions of friction increases and the other diminishes, and this too at very different rates.

For all practical purposes, however, we need not perplex ourselves thus; for in nine cases out of ten the sod has no elasticity whatever; and I believe in almost—perhaps in all—cases, when it has elasticity, the limit before alluded to, which is put to the shortening of the mould-board by the angle of repose of soil on iron, will insure to the mould-board a length greater than what would be given to it on a review of the influences respectively of the weight and of the elasticity of the sod—the one anxious to shorten and the other to lengthen it.

Were there no other matter for consideration, this would at once determine the question of the form of the mould-board of least resistance; for we have only to ascertain the length of the mould-board, such that the angle which its surface makes with a vertical plane across the direction of the plough's motion may always be more than the angle of repose of soil on iron, and then the surface of uniform curvature of this length, which commences with a horizontal line where it joins the share, and terminates with a straight line hanging over beyond the perpendicular at an angle of 45° will be the surface of least resistance, which will answer all those conditions required of a good mould-board.—*M. S.*

THE ISLAND OF LEWIS.

At a late meeting of the Glasgow Philosophical Society, Mr. Smith, late of Deaston, gave the following details of a visit to that island:—Lewis is the most northerly of the western group of Scottish islands, and though generally spoken of as a distinct island, is nevertheless connected with Harris by a narrow neck of land, from which circumstance they are sometimes called the long island. The rocks are of the primitive or granitic formation; and the surface of the country has altogether a very peculiar aspect. It appears that the peat moss has begun to be formed immediately upon the granite rock; for when you get to the bottom you find at once a rough gravel, mixed with small quantities of clay, and hardly such a thing as a distinct alluvial deposit. The whole surface is covered with bog, from 2 to 10 feet, and in some places 20 feet in depth; although the general depth may be stated at about 4 feet. Upon the surface of this bog nothing grows but Bent Grass and stunted Heath: it has a very dreary aspect. Not a tree is to be seen; and in the after part of the year, when the Bent becomes decayed, the appearance is peculiarly black and desolate indeed. The most remarkable thing connected with the island, however, is this—that the slightest improvement does not appear to have gone on for a very long period. The inhabitants still use the ancient distaff, although it is 100 years since it has been supplanted in this country by the Dutch wheel. The advantages which the best machinery of the day possess over the distaff, are as 1000 to 1; yet, by means of the distaff, these people manage to manufacture their cloth, which, under the circumstances, is very comfortable. Their cultivation of the soil is as primitive as their manufacture of cloth. The holdings are very small, the island has been for 50 or 60 years in the possession of proprietors who had no money to improve, or with which to encourage the people; and to this, in a great degree, their present primitive state is to be attributed. Their possessions extend only to a few acres each; and the people are congregated in villages or little towns, instead of being dispersed in farms over the face of the country, as is the case elsewhere. They have, therefore, their little portions of land around for cultivation, and a right to grazings in the neighbourhood. In regard to their houses, they do not live in dwellings such as are seen in the mainland, for they are more like huts than anything else. The walls are from 6 to 8 feet thick, composed of bog in the centre, and faced with stone inside and out. There is sometimes only one apartment, but generally two, and under the same roof the people live and keep their cattle. There is, however, a fall of 18 inches from the apartment in which the family live to the adjoining one in which the cattle are kept. This may seem to some to be rather a queer arrangement; but the people themselves consider that there are points in it which contribute to their comfort. The room in which the cattle are kept is the entrance one, and as the air passes through it, it comes into the adjoining portion of the house, appropriated to the family, in a warm state. Where ponies are kept, an outer hall or shed, beyond the cattle apartment, is reared for their accommodation. Some of the better houses have a division wall, which separates the cow-house from the family apartment; but generally this is not the case. Most people would think it strange to live along with their cattle; but the people of Lewis have different notions on the subject, and when shut up in the long winter nights, they consider it comfortable to have the beasts in the next apartment, to hear them, and see their motions, and occasionally to supply them with food. One peculiarity in the building of their houses is, that the roof is within the wall, instead of projecting beyond it; and in this way something like a series of terraces sometimes extend over half a town. One use of them is, that when the children become troublesome, or the mother is more than usually busy, the children are disposed of on these terraces or high places, and it is quite amusing to see the little whitterets looking down over the wall at what is going on below. The parents, however, do all this in the most kindly manner. They have done all they can to cultivate their little possessions in the best manner. Their cultivated portions are those from which the peat has been cut away; they then come to the gravel, and gather soil from one part to add to another. Two-thirds are taken from one part and added to another third, and thus a soil is formed; but in winter a complete pool is formed between these ridges of soil. They have done nothing in the way of draining; they have never attempted to penetrate the hard subsoil, which is often steeped in water. They have no system of winter ploughing, but just move the land immediately before planting the Potato crop or sowing the seed; and the only preparation they make is that of sometimes pulling the weeds in the summer season. Mr. Smith then described some of the implements in use among this primitive people. He exhibited the "crass-croom," or hand and foot plough. It is an instrument with a sole about 15 or 18 inches in length, thick behind and sharp in front, which latter, being the part which first penetrates the soil, is shod with iron. It is pushed forward by means of a long handle fixed into it, and also by a pin attached to the heel of the sole or sock, for the foot of the labourer. A more unlikely implement to have the name of a plough it is scarcely possible to conceive. The people lay the land over in furrows, by successive movements of hand and foot, but of course the line is not drawn in a continuous form. When two of the neighbours have a pony each, they occasionally use another kind of plough, with only one stilt, the beam of which rests on the ground. Mr. Smith exhibited this implement also, which appears to be scarcely a step in advance of the other. The great difficulty in providing their implements is the scarcity of timber, of which none grows in the island, and they have consequently to send to the mainland for it. As a proof of its value, the shaft or handle of the "crass-croom" (which is a piece of wood about the size of a broomstick) costs 3s. 6d. From the scantiness of the soil, they do not, of course, produce heavy crops. Good produce of Potatoes, Barley—or rather Bear or Bigg, for the new kinds of Barley are unknown to them,—and Oats, however, are sometimes obtained, and they manage to produce these results by the skill with which they prepare the manure. It is efficacious, in the first instance, in the raising of Potatoes, and afterwards it produces a fine Barley crop. When the Barley is ripe, they do not cut it as elsewhere, but pull it up by the roots, and tie the whole up in sheafs. When it is "won," and ready for the stack, the straw is then cut from the sheaves below the band, which has this advantage, that it enables them to stow away the grain in small bulk—a matter of no small moment in a country exposed to so much wind and rain. After the grain itself has been thus preserved, they take the straw which has been cut from it, and place it on the roofs of their houses. They lay it loose on, just as the farmers here spread it over the tops of stack, and then tie it down with ropes spun from the Heath. In this position it is exposed to the smoke of their peat fires. The fire is placed in the middle of the room, and there are no vents; but instead of this, a number of holes are ranged all around the top of the side wall. When the smoke ascends, therefore, and a portion of it is forced back, it escapes by means of these holes. A great deal of it, however, makes its way up through the straw on the roof, and when approaching one of these little towns, its appearance is to nothing more like than that presented by the smoke rising from a cluster of heated grain-stacks. This straw becomes very valuable, from the great condensation of ammonia and other products which takes place in it. The people of Lewis plant their Potatoes without any manure whatever; but when the plant has got up to the length of 2 or 3 inches, a general unroofing of the houses takes place, and the straw which has been preparing there all the season is thrown upon the drills; it is rarely covered up, excepting in windy weather, when a slight sprinkling is put upon it to prevent its being blown away. Well, this manure gets into the soil immediately, and the Potatoes forthwith come up with the greatest luxuriance. Indeed, if guano were to be scattered on the soil, the effects would not be more rapid or complete than those produced by this prepared straw. This certainly evinces great ingenuity on the part of these people, who from the difficulties of their position, are driven to it as the only means of preparing manure. The people of Lewis, however, have also the manure produced from their cows, and their care of it evinces a degree of intelligence superior to that of farmers of much higher pretensions, for they keep it constantly covered up, and all join in the opinion that if it was exposed it would lose, to a great extent, its efficacy. When the manure, therefore, is taken out of the house for one crop, they immediately commence to accumulate for the next, and thus they keep adding to its bulk, till it is needed for the Potatoes or Barley. It may seem strange that the people should live in the next apartment to so much decaying matter; but the people feel no inconvenience from it. At the time, however, the manure is taken out, fever often prevails amongst the people, which is only attributable to this cause. Some of our best agriculturists are about to follow this plan of keeping the manure constantly covered up; I do not say that they should live in the same house with it, but it is of great moment that the manure should be constantly under cover. In Lewis they certainly follow a strict rotation of cropping. They have first Potatoes, then Barley or Bigg, then Oats—constituting a three years' shift. According to this rotation they had grown their crops for 100 years, and one might naturally suppose that the lands would be worn out by it; but this is not the case, for they had generally fair crops, and last year it was an extraordinary one. The Potatoes were good; and as to the Barley, though dark in the straw, it presented in a marked manner that golden appearance which indicated a healthy yield. On the whole, there is no doubt that if these people were properly directed in the best modes of cultivation, they would, with their habits of industry, make rapid progress. Happy days, it is believed, are yet awaiting them, for they have now got a gentleman connected with them who devotes his money to work out the improvement of their country, and otherwise promote their welfare. On their shores there are millions of tons of shell-sand, which is so nicely pulverised that it can be at once applied to the soil. It would, no doubt, be much improved were it calcined or burned, and mixed; but even taking it in its native state, great advantage will be derived from its application to the ground. There is no lime or coal, but the want of the former would be made up by this shell-sand, if they could only get easily at it. It lies amongst the perpendicular rocks around the island; and as there are no roads, the difficulty of procuring and transporting it is very great. When the roads are made, however, means will be taken by which the inhabitants will avail themselves of these deposits, and they will form a material element in fertilising the soil. So much for the agriculture of Lewis. As to their manufactures, they make their own dishes or vessels from the clay found amongst the granite gravel. They fashion the vessel merely with the finger and thumb; and the strength and thinness with which they are made, prove the quality of their clay. They turn over the neck of mouth, and by putting a cord, or rather a leather thong, round it, they are enabled to carry them from place to place, containing water or milk; and they also stand the heat requisite to boil their contents when placed on the fire. They also make their creels, for carrying out their manure, and for other uses; and the audience will be surprised to hear they are made of the stem of the Dock. So much is this plant prized amongst them, that when it grows between the possessions of two farmers, the Docks are carefully divided between them. There is not a Willow in the island; and the Dock, therefore, is very much prized for its usefulness. Another mode of the people of Lewis is that of feeding their cows on sea-ware. It is just the dulse tangle, which is often seen sold on the streets of Glasgow; and it is no unusual thing, when a woman goes out to milk the cows, to take some of this dulse or tangle, which the animal consumes with great satisfaction when the process of milking is in progress. The cows often seek it for themselves on the seaside, especially in seasons when Grass is scarce. There are some seasons, indeed, when they almost entirely live upon it. At one time a large revenue was drawn from sea-weed from converting it into kelp; but from the various changes it has fallen in value from about 20*l.* to 2*l.* 10*s.* per ton. It does not, therefore, now pay for the

manufacture of kelp, and it is therefore better to apply it to the soil. Forty tons of sea-ware are equal to one ton of kelp, and twenty tons of this sea-ware is quite enough to dung an acre; this is 25*s.* for manuring an acre, and doubtless this sea-ware will come more and more into general use for the purposes of cultivation. The lecturer then exhibited a large bag in use in Lewis, which was made of the stem of the Bent Grass, and spun in the long winter nights; they are used for keeping the corn in, and carrying such portions of it to market as they are able to spare for sale. There is a distillery on the island, which takes up all the surplus of the Barley crop. After giving a few geological details, Mr. S. stated that the population extended to 12,000 souls, and there were 270,000 acres of land, which, if improved as it might be, would maintain twice the number of people in more comfort than they were at present.—*Abridged from the Scottish Guardian.*

SKETCHES OF EAST LOTHIAN HUSBANDRY.

Live Stock.—East Lothian being essentially a Corn-growing county, grazing is carried on only as subservient to tillage, and the rearing and management of live stock is therefore regarded as an object of secondary consideration by most of the farmers. Cattle and sheep are fed to a considerable extent, but comparatively few of the former are reared in the county, the greater number of them being purchased annually at Falkirk Tryst, Allhallow Fair (held in Edinburgh), and other markets; only a very few farmers keep more milch cows than are sufficient to furnish a regular supply of dairy produce for their families. Each hind or servant having a house, has also a cow supported for him throughout the year on the farm in which he works. No oxen are employed in farm labour, every description of work at which beasts are employed, being performed by horses. The attention of the intelligent agriculturists of this county not having necessarily been so much directed towards the rearing and improvement of cattle, as in other districts where these animals form a more important branch of farm management, the stock farming of East Lothian does not exhibit much deserving of commendation. There are, however, several exceptions to this, as many fine specimens of the short-horned breed are reared in different parts of the county; a circumstance confirmed by the fact that many of the prizes awarded at the Highland Society's Show in Edinburgh were carried off by East Lothian farmers.

The method of feeding usually practised is to allow the cattle, in lots of five or six, or more, according to their age and size, perfect freedom in open courts or yards provided with sheds, to which they may retire for shelter in inclement weather. Each yard has along one or more of its sides a range of shallow troughs formed of wood or flag-stones, about 3 feet high, from which the cattle eat their Turnips or other food. Oil-cake and Bean-meal are used to a considerable extent as auxiliary to Turnips in fattening off cattle in spring. As has been already observed, many farmers let the greater portion of their Turnip crop to cattle-dealers, either at a certain price per acre or at an agreed rate—now 4*s.* to 5*s.* a week, for each beast.

Permanent and extensive flocks of sheep are almost confined to the Lammermoor district—the upland part of the county. The kinds kept there as being the best adapted to the situation, are the black-faced and Cheviot breeds. Improved Leicester sheep are common in the low parts, as are also the Cheviot. Crosses between the last named breeds are held to be better adapted to the soil and climate than pure sheep of either of those kinds. In the low district sheep are kept chiefly to consume a portion of the Turnip crop on the ground; black-faced hogs are most generally preferred for this purpose, as their mutton is most esteemed, and obtains the highest prices in the market. Turnips are also frequently sold to dealers to be eaten by sheep, either by the acre or at an agreed rate, generally 5½*d.* a week for each sheep. These are commonly purchased in autumn, and again sold off when ready for the butcher. A very considerable number of lambs are brought up for the supply of the Edinburgh market, and many are annually shipped for London.

The horses generally kept are of moderate size, combining much strength with activity, and partaking largely of the Clydesdale breed. These animals receive much attention, and are, generally speaking, maintained in good condition, *i. e.* equal, if not superior, to the work which they have to perform. A pair of stout horses are allowed to be capable of working 60 Scotch acres of land of an average quality. The following is the mode of feeding and managing farm horses generally adopted in the Lothians:—About the beginning of May they are turned out to graze at nights, but receive their usual allowance of Corn—three feeds of about 4½lbs. each, with a limited quantity of hay during the mid-day rest; very little hay is used by the farm horses, but what is given is always reserved till the period of hard work attendant on the preparation of the land for green crops. This management is continued until the Clover is ready for cutting, the horses are then kept in the stable during the night, and receive a limited allowance of cut Grass. When the Turnip seed is all sown, and the fallow land (if any) finally ploughed and worked, the horses are again turned afield, where they remain day and night until the carrying of the Corn-crop commences. Green Clover being then generally consumed. These are substituted during harvest, the horses being still kept out over night till the ploughing of the stubble, or of the land for autumn-sown Wheat begins; they then receive their full winter's feeding—about 14lbs. of Corn, with straw *ad libitum*; four bushels of Oats is the general allowance to a pair of horses in the week. Most farmers give a boiled mixture of Beans and Barley, two or more nights a-week; and instead of giving the Corn entire to horses, it is not uncommon to bruise or break it with an apparatus for the purpose, driven by the same power that propels the threshing machine. A few Swedish Turnips are given daily to each horse during the winter and spring months, which tends very much to their improvement. These are, no doubt, many little deviations in the practice of different farms, but the above is the general management of farm-horses adopted in this county, and indeed throughout the south of Scotland. There is, perhaps, too little attention paid to cleanliness in the stable; and it is a fact generally observed by strangers, that the harness of the farm-horses here is much inferior in appearance and quality at first, to that commonly met with in other parts of Scotland, and that much less pains are taken by the servants in keeping the harness belonging to their horses clean and in good order. This carelessness is supposed to arise in a great measure from the circumstance that those working with horses are, for the most part, married servants, who are generally found to possess less taste for neatness in this respect than younger and unmarried men. In spring and summer the time of working is nine hours a day, except at seed-time and other hurried occasions, and in winter from daylight to dusk, with an interval of an hour for dinner at 12 o'clock; but in many places it is usual to go six hours at one yoking during the short days of winter, and to lessen the quantity of Oats given to the horses; while in other parts the customary practice is to corn the horses and take dinner in the fields, to avoid the loss of time occasioned by going to and returning from the stables.—*T. Sullivan.*

Home Correspondence.

The Allotment System now appears to be caught at as the remedy and panacea to meet the distresses of the labouring poor. "Drain, drain your land and give employment," is now the cry. "Subsoil and turn chemist, to find out the food best adapted for your different soils, and you will enrich yourselves beyond belief;" for so says the enthusiast. Suppose this to be true—and I do not question but the man who has a knowledge of chemistry, and a purse, to drain and subsoil, may increase his crops marvellously—I ask who is to start these schemes? Why, the landlords to be sure; few tenants have the means. It is all very fine talking of the landlords laying the foundation of good crops on their tenants' lands by draining, and getting 5 per cent. for doing so. But many owners of property are as poor as the tillers of it; and others are unbelievers in these plans, or excuse themselves under various pleas. Some say, "Give the tenants leases, for they would spend their capital and give employment, and embark with zeal in the new system so generally recommended." And some there are that would do so; but as I take it, with the plurality even of these, there would be many things wanting to bring about the desired end; for education, as far as I can see, has not travelled very rapidly in the agricultural provinces; besides, how few tenants have capital, if it had. I am no friend to leases; 9-tenths of them are dropping in, with the farms little better, often worse, than they found them. And what is the allotment system to do? The answer is glibly given—"It will ameliorate the condition of the poor." There are many difficulties in practice connected with this new scheme. It often disgusts the man, striving to assist his labourers, to find in numbers, how many are unwilling to help themselves, and how many are careless of your consideration. Certainly, many are benefited by holding a piece of land, and comfort, health, enjoyment, and comparative wealth, bless many a family that cultivates it well; but how few are there of such! How many smile and say, "What new crotchet now has the squire got into his head?" How many do not pay, and say it does not answer! How many tell you, "How can I find strength (poorly fed) to work from six to six on my master's farm, and then set to work upon my own?" The wife has indoor work, and children to look after; but there are many men who think feelingly that digging and delving for a woman is bordering on slavery. Suppose a nobleman or gentleman kept 50 labourers, and to each he gave an allotment of land; to see that they observed all the rules laid down would occupy much of his or the bailiff's time, which possibly would be cheerfully given if the results would turn out beneficial to all parties. As the seasons are the same for all, and so are the preparations for planting, sowing, and in the end reaping, the one interest, I apprehend, would greatly interfere with the other; and for the landlord in the midst of his own harvest to be asked by his labourers for half and whole holidays to do their own work, appears to me likely to create unpleasantness. If [*if I*] a labourer can get work all the year round, my advice to them would be to stick to it, and that alone; for the goodness and benevolence of the old country gentleman still exists in our landed proprietors—they seldom turn adrift the man in short winter days, or when the sere and yellow leaf is come upon him. It is not with them to cheapen wages, and grind them down, and use them only for their own profits.—*L. L.* [These oft-repeated objections to the system are sufficiently refuted by history and fact. See the "Labourers' Friend" for August, September, October and November, 1843.]

Services of the Rook.—A strong prejudice is felt by many persons against rooks, on account of their destroying grain and Potatoes; and so far is this carried, that I know persons who offer a reward for every rook that is killed on their land; yet, so mistaken do I deem them, as to consider that no living creature is so serviceable to the farmer, except the live stock he keeps on his farm, as the rook. In the neighbourhood of my native place is a rookery belonging to Wm. Vavasour, Esq., of Weston, in Wharfedale, in which it is estimated there are 10,000 rooks; that 1 lb. of food per week is a very moderate allowance for each bird; and that 9-10ths of their food consists of worms, insects, and their larvæ. For, although they do considerable damage to the fields, for a few weeks in seed-time and a few weeks in harvest, particularly in backward seasons, yet a very large proportion of their food, even at these seasons, consists of insects and worms, which (if we except a few Acorns and Walnuts in autumn) form, at all other times, the whole of their subsistence. Here, then, if my data be correct, there is the enormous quantity of 468,000 lbs. or 209 tons of worms, insects, and their larvæ, destroyed by one single rookery; and to every one who knows how very, very destructive to vegetation are the larvæ of the tribes of insects (as well as worms) fed upon by rooks, some slight idea may be formed of the devastation which rooks are the means of preventing. I have understood that in Suffolk, and in some of the southern counties, the larvæ of the cockchafer are so exceedingly abundant that the crops of corn are almost destroyed by them, and that their ravages do not cease even when they have attained to a winged state. Various plans have been proposed to put a stop to their depredations, but I have little doubt that their abundance is to be attributed to the scarcity of rooks, as I have somewhere seen an account that rooks in those counties are not numerous, either from the trees being felled in which they nestled, or that they had been destroyed by the farmers. I am the more inclined to be of this opinion, because we have many rooks in this neighbourhood where the cockchafer is not known as a destructive insect, and I know that insects of that class, and their larvæ, are the favourite food of the rook. I will mention another proof of the utility of the rook, which occurred in this neighbourhood many years ago. A flight of locusts visited Craven, and they were so numerous as to create considerable alarm among the farmers of the district. They were soon, however, relieved from their anxiety, for the rooks flocked in from all quarters by thousands and tens of thousands, and devoured them so greedily that they were all destroyed in a very short time. It was stated in the newspapers, a year or two back, that there was such an enormous quantity of caterpillars upon Skiddaw, that they devoured all the vegetation on the mountain, and people were apprehensive they would attack the crops in the inclosed lands; but the rooks (which are fond of high ground in the summer) having discovered them, in a very short time put an end to their ravages.—*T. G., Clitheroe, Lancashire.*

Tusser's Husbandry.—Sir Joseph Banks left all his MSS. to the British Museum. I recollect at the time there was much discussion as to whether all his papers had found their way to that depository, especially a copy of "Tusser's Points in Husbandry," to which the indefatigable baronet had added many valuable notes, containing his personal observations. I think Sir H. Ellis was employed in preparing this for the press. In these times such a work would be very interesting. Can any one give any information on the matter?—*Dodman.*

Potato-seed.—In your Paper of the 23d inst. "A Farmer" wishes to know the best time to gather, preserve, and sow Potato-seed. I beg to say that the time of gathering is any time from that of the apple's being fully ripe to the present: gather them, and store them in tolerably dry soil, either whole or bruised; keep them in the ground from frost, and in March or April take and mix the soil in which they have been kept, and sow altogether and cover with light soil about a quarter of an inch deep.—*John Jackson.*

Malt Tax.—The consumption of malt for a century previous to 1830 remained nearly stationary, although the population had increased more than three-fold, but, in consequence of a repeal of beer duty in 1830, we find that the consumption of malt by public brewers was in that year only 2,649,471 qrs. of malt, but in 1840 was 4,082,367 qrs.; the government in 1840 increased the duty on malt and Hops 5 per cent., and we find that in 1843 the consumption of malt by brewers had fallen to 3,566,298 qrs., thus showing that with a duty of 20*s.* 8*d.* per qr. on 4,082,367 qrs. in 1840, the government received a revenue of 4,218,445*l.*; in 1843, on 3,566,298 qrs., at 21*s.* 8*d.*, 3,683,489*l.*; showing a loss of 354,956*l.* by the increase of duty; whereas the 5 per cent. ought to have increased the revenue by 204,110*l.*, supposing we had no increase of population from 1840 to 1843, and that the consumption had remained the same; whereas the former had increased by full 600,000 persons, and the latter had decreased by 354,956*l.* Again, we find that 5 years previous to the 5 per cent. duty being laid on Malt and Hops, the average number of acres cultivated for Hops was about 54,500; in the last 5 years 44,500; showing a decrease of 10,000 acres during the last 5 years as compared with 5 years previous; this, alone, is a serious injury to the labourers employed in producing Hops, and also a serious loss to the revenue, for during the 5 first years the average amount of revenue derived from Hops was about 345,000; during the last 5 years, with increased duty of 5 per cent., only 228,000*l.*; showing a loss of 117,000*l.* per annum by the increase of duty. Now, the object of taxes I imagine to be, to raise and increase the revenue, and not to decrease consumption, for this last might be effected by a positive and prohibitory law. The object, therefore, of the 5 per cent. duty is manifestly nullified; for we see, that as

the duty is raised, so the consumption, and therefore the revenue is decreased. Of course it is easy to see that any decrease in the consumption of an article would be the means of throwing out of employment those whose occupation is connected with it; and we now find our Union houses overflowing with persons seeking employment, who, by a total and immediate repeal of the Malt-tax, would be provided with work, and with one of the chief necessaries of life to those who are engaged in arduous and manual labour.—*A Tenant Farmer.*

Drainage and Irrigation.—In the last Number of your Paper, "A Leicestershire Farmer" observes—"It appears possible to double the value of some districts by draining alone." In the village in which I reside I see a specimen of improvement by draining. There are 18 acres of meadow and 20 of pasture. Before alterations were commenced, the meadow-land was considered of average quality—some parts very rough, and full of hassocks—[What are *they*?]—while the produce of the other parts was good, but never very large. In the winter, during wet weather, it was always flooded; the brook was small and circuitous in its course, and this, which caused it to overflow, hindered the water from rapidly subsiding. It was not drained deep, and consequently, during the winter, was always wet, and considered an admirable place to rot sheep. So much for it in its primitive state. In the autumn of 1841, the owner commenced his operations. The channel of the brook was altered, the whole of it was deep-drained—in some parts 5 or 6 feet deep; the surface made perfectly level, and carriers formed for irrigation. One brook takes its course down the middle, and another on its higher side; and it can be irrigated during the winter, and after heavy rains in the summer. The subsoil is a stiff, tenacious clay, and the neighbours thought the owner a great fool for expecting to find water in such a bottom; the owner's anticipations, however, proved correct. At the depth of from 4 to 6 feet, he found beds of sand and gravel, whence issued a spring, in many cases not very strong, but which rose to the surface when the intervening beds of clay prevented them from draining. 15 out of the 18 acres are inclosed in one meadow; the remaining three, which were a bog, being a paddock. The improvement of the meadow cost 17*l.* per acre. The owner was regardless of expense, and some things might have been done in a more economical way, but he thought the most substantial way would, in the end, be the cheapest. In 1842 much good was not expected, as a great portion of the turf had been moved, and a large part was not finished till late in the spring. During the winter of 1842 it was irrigated, and in March 1843 it was stocked with sheep; for the months of March, April, and May, it kept more than 100 sheep, a few beasts, and the ewes with couples. It was again irrigated and mown in the middle of July; again irrigated and mown in September, bearing larger crops than ever had been known in it before. It went through the same process in the winter of 1843, and, I think, this year was stocked in February, and kept a larger quantity of stock for three months. By the time the Grass was eaten off, the dry season had commenced, and it was not possible to irrigate it; and, therefore, there was no more in it than in other meadows; though, after it was mown, there was a good after-math. After the first heavy rains, it was irrigated and mown in October; a very good crop, though, unfortunately for the owner, it was very wet weather, and he sent all his stock, and had most of it consumed by them; and they were very willing to eat it after the dry summer. The pasture-land of which I spoke, was, before draining, of good average quality; but I think I speak within bounds when I say one-third was Rushes, and in winter it was so wet as to be impassable after rain by a pedestrian. It was drained in a manner similar to the meadow, and was found to be in a similar state. In this case the expense amounted to between 7*l.* and 8*l.* per acre. The whole had years ago been drained with tiles about 15 inches deep, and therefore this dry that it was impossible to get rid of the Rushes without ploughing. The Rushes gradually diminished, and last year, 1843, there was an immense crop of Grass; this spring it was stocked till after the dry season commenced, and it never grew till the rains in the autumn. There is, however, scarcely a Rush to be seen. I should conceive the whole expense has been about 600*l.*, and the owner has let his farm at 30*l.* a year more rent than he had before. The farm is only 100 acres in extent, and no other material alterations have been made, as the owner has only had it in his own occupation five years. The arable land has been improved by cleaning, and by having more manure applied, which manure was obtained by stall-feeding, and by cutting and steaming the food during winter; but I have allowed 5*l.* for that improvement. You will observe I do not speak positively—I am merely a looker-on; but any information asked for was always given me.—*A Leicestershire Yeoman.*

Mr. Smith, of Deanston.—I have a letter now before me, dated December, 1824, from my early friend and benefactor, James Smith, Esq., of Deanston, now of 13, Queen-square, Westminster. It tells me that he is draining the whole of the Deanston farm, which I knew to be nothing but a morass, where the greyhounds sunk to the second joint every step they took; and that in a very short period, by good management, with proper draining and subsoil-ploughing, it could be brought from a condemned farm, not worth more than 5*s.* per acre, to be now let at from 2*l.* 10*s.* to 3*l.* per acre is most astonishing. Mr. S. was at that time everybody's friend, rich and poor; his advice was courted by all; all differences that were likely to lead to anything serious were settled by Mr. Smith; and I believe the greatest loss that Deanston, and the neighbourhood ever had, was the leaving of this much esteemed gentleman. He was manager of all those extensive works at the early age of 22 at that period he showed great powers as an engineer, and he is now carrying out to the fullest extent, and in the most skilful way, his draining and subsoil ploughing all over Great Britain and Ireland; and through his great knowledge no man can be better qualified, for his heart and soul is in improving the land; and my earnest prayer is, that long before he closes his eyes, he will have the pleasure of seeing every acre in Great Britain and Ireland producing double to what it did when he first began upon the Deanston bog—misnamed a farm.—*James Cuthill, Florist, Denmark-hill, Camberwell, London.*

Lucerne.—Your advice to "Delta," as to the mode of cultivating Lucerne, page 808, is not good. Lucerne should be planted in well-trenched ground, in drills, 2 feet at least apart, and the plants should be 12 inches, at least, apart, in the rows. If "Delta" pursues this plan, putting in the seed not earlier than the last week in April, thinning them to the distance I have stated as soon as they get well out of their first leaves, he may cut the Lucerne at least twice in the first year. I think 30 inches between the rows, and 15 between the plants, a better distance; but that is mere opinion. At the distances I have named, I planted Lucerne on the 1st of last May, and although, from the extreme drought, it was for some weeks so entirely at the mercy of the fly, that I was near ploughing it in, yet when once it got good hold of the ground it grew so rapidly that we have cut it three times—the two last, heavy crops, some of the roots having by that time 70 distinct stems, and none less than 40. I find constantly many valuable hints in the *Chronicle*, and generally adopt them. Doubtless there are many who pursue the same course, and I have therefore thought it right to trouble you with this. Lucerne, properly grown on land to which it is adapted, is perhaps the most valuable of all crops for cattle-feeding, and everything should be done to promote its greater cultivation.—*Frederic Kelly*, 49, *Hunter-street.*

Societies.

ROYAL AGRICULTURAL SOCIETY OF ENGLAND.

DR. PLAYFAIR'S FIRST LECTURE.

The first of the Annual Lectures of this Society was delivered in the Theatre of the Royal Institution, on Wednesday evening, the Duke of Richmond, President, in the chair. There was a large attendance of Members, and we observed present the Marquis of Northampton, Lord Spencer, the Marquis of Downshire, Lord Essex, Dr. Buckland, Dr. Daubeny, Dr. Falconer, Prof. E. Forbes, Dr. Day, P. Pusey, Esq., M.P., Sir O. Mosley, E. Chadwick, Esq., and other distinguished Members of the Society and men of science. The Lecturer commenced by pointing out the value of the principles of science, as a guide to the practical details of art. In the present lecture he should give an outline of those scientific principles which could alone safely guide the practical man in the new features of his art. In the second he should apply those principles. Experience was by some regarded as the only guide in practice; but there were many cases in which experience could suggest no alternative in practice, and here science stepped in to the aid of the practical man. The farmer in Virginia had found, by the experience of a hundred years, that his land would grow Wheat every year; but, when his land failed to do this, his experience suggested no alternative. In other parts of America the soil had afforded nutriment to alternate crops of Wheat and Tobacco; but at last the soil failed to grow either, and individual experience was of no value. The question for the Americans to consider in these cases was, Can we again make our land grow Wheat and Tobacco as it has done? and this could only be answered by science. The answer was, that these crops had exhausted the soil of ingredients necessary to their existence, and these ingredients must be again supplied. It was the same in certain counties or districts in England; the land failed to produce certain crops in a given time, and the season could only be ascertained by scientific inquiries. It would be vain for the farmer of light lands to suggest to the cultivator of a heavy land the expedients he had found of avail in restoring the fertility of his soil, and *vice versâ*. Such differences existed in every district, and the cause of these differences could only be ascertained by scientific inquiry. It was only by a combination of experience and science that the object of the pursuit of the farmer could be obtained, and for that object this Society had been instituted. Before proceeding to theory, he would make a statement of the constituents of the soil required by plants; these were:—Silica, alumina, lime, magnesia, iron, potassa, manganese, soda. These bases were combined with sulphuric acid, phosphoric acid, chlorine, fluorine, iodine, bromine, carbonic acid. These were the ingredients with which the soil was stored, and out of which the whole vegetable kingdom had been formed. These constituents existed at the creation of the world, and it was from these that the primitive forests and plants of the world had been created. What took place on a large scale in the field of the world, must also take place on the field of the farmer. It was from Nature we must learn the principles of farming. The constituents out of which plants were formed existed in the primitive rocks, from which every other strata was formed. These rocks consisted of granite; and granite was a compound of substances, known under the names of felspar, mica, quartz, and hornblende, (specimens of granite, and these constituents of it, were exhibited). Now, in these rocks all the substances that entered into the composition of plants existed. Chemists had not examined these rocks accurately. Phosphate of lime had not been supposed to be a constituent of granite, yet late researches, especially those of Dr. Daubeny on the rocks of Estremadura in Spain, proved that there was considerable quantities of phosphate of lime in these primitive rocks. Common salt, chloride of sodium, had not been found in these rocks, but it existed abundantly in the waters of the ocean. The carbonic acid needed by plants existed in the atmosphere, and also in the waters of the sea. The inquiries of Brande rendered it exceedingly probable that carbonic acid existed in much greater quantities in the air and in the seas of primitive states of our globe than at the present moment. The carbonic acid of the water must have played a most important part in the original economy of creation. It was only by its means that the alkalies and earths could have been dissolved out of the primitive rocks. When these constituents were dissolved, the great mass of the rocks over which the waters rolled would be easily disintegrated, and the particles of silica and alumina would then be deposited in another form. It was thus that the three principal constituents of our present soils were deposited. The silica being deposited formed the sandstone rocks, and gave the character to arenaceous soils; the alumina formed the clay beds and argillaceous soils; the carbonate of lime the limestone strata and calcareous soils. There had been a question as to how these latter rocks had been formed. The carbonate of lime (chalk) was an insoluble substance, and did not exist to any extent in the primitive rocks, but it was easily formed by the union of carbonic acid and lime. It was a property of carbonic acid that, when diffused in water, it would dissolve carbonate of lime; it was thus held in solution in the first water. If the carbonic acid was in any way separated from the water, then the carbonate of lime was deposited. Mr. Lyell had supposed that all the limestone beds were deposited from springs from under the surface of the earth, which, coming up charged with carbonic acid and carbonate of lime, the former escaped on coming in contact with the atmosphere, and the latter was deposited. But the limestone beds gave evidence of being deposited at the bottom of tranquil seas. They contained remains of animals, and before animals could live, there must be plants. Now, one of the principal constituents of the food of plants was carbonic acid, and he (Dr. Playfair) would suggest that it was the marine vegetation of those periods which, taking up the carbonic acid of the waters, caused the deposition of carbonate of lime. It was no argument against this view, that remains of plants were not found in limestone beds, as Dr. Lindley had proved that decaying vegetable tissue was quickly reduced to its elements before any deposit could be formed to seal its existance. The animals which existed at the time, afforded to the chalk its phosphates, and the analysis of chalk nodules proved that they contained this ingredient. It was not, however, the fact, as some geologists had supposed, that the limestone beds were formed entirely by animals. Some had asserted that chalk was composed entirely of infusoria, and it was from these and other animals that the chalk obtained its silica; but the chalk could not be composed entirely of infusoria, as their function indicated. One function of infusoria, hitherto unexplained, was the undoubted fact that they gave out oxygen. This was exactly the contrary of what other animals did. They only existed where the higher forms of animals or plants were decaying, and where they existed they indicated this fact. They were the scavengers of nature, and acted as purifiers, just the same as the fungi did on land. The fungi existed by means of decaying vegetable and animal matter, but they differed from infusoria in giving out carbonic acid. This was a curious fact, that the lowest animals performed the function of the highest plants, and that the lowest plants performed a function in common with the highest animals. But other means were taken to prepare the soil from primitive rocks, so that the secondary ones should become a fit theatre for terrestrial animals and plants to live upon. The rocks were thrown, by volcanic action, above the surface of the water, and then, by the action of the oxygen of the atmosphere, the carbonic acid, rain, and frost, they were decomposed, and their elements entered into combinations fitted to become the food of plants. The iron of these rocks underwent changes. Iron existed in nature in two forms, that of the protoxide, or one proportion of oxygen and one of iron; and that of the peroxide, with two proportions of iron and three of oxygen. The former was injurious to vegetation, and to animal life; the latter was beneficial and necessary. The protoxide could be converted into the peroxide by the absorption of oxygen from the air, whilst the peroxide was reduced to the protoxide by action of decomposing organic matter. This was an important practical fact. It went on, on a great scale in nature. The blue clays of the lias and coal-beds, where there was much organic matter, always contained the protoxide. The red sandstone contained the peroxide. A curious instance of the formation of the protoxide had been observed by Mr. Binney, of Manchester, in the coal-measures about that neighbourhood. Wherever shells were found open, where there is occasion to suppose the animal escaped, the rock in which it was embedded was red, indicating the presence of the red or peroxide of iron; but where the shells were closed, and the animal had gradually decomposed, it was blue, indicating the protoxide; which had been formed by the decomposing matter of the animals. In the red sandstones there was the peroxide; and one important fact regarding this substance was that it had a great affinity for ammonia, which it absorbed, and could be detected in all

red sandstones. The sandstones and the limestones were thus replete with matter ready-formed to be used as food for plants. Succeeding to the period of their formation was that of the great vegetable era in which the coal beds were formed. The effect of the decomposing vegetable matter on the peroxide of iron was remarkable, and worthy of attention. When the plants began to decay, they converted the peroxide into the protoxide, and when this latter was formed, it acted injuriously on vegetation and destroyed it. It was thus, he believed, that great beds were formed at the present day; the decaying plants converted the peroxide of iron into the protoxide, and when this ingredient was formed it destroyed the remaining living plants. The blue clays deposited underneath Peat-beds was a proof of the correctness of this view. The peroxide was, however, easily convertible into the protoxide by exposure to the oxygen of the atmosphere. It was by subsoil-ploughing that the farmer could render available his blue clays for the nutrition of plants. It was thus that Nature came with her great subsoil-plough, the ocean, and threw up on the shores the injurious protoxide in the form of a peroxide, as well as effected other important changes. Now the farmer might learn a great lesson from this way in which Nature acted in preparing the constituents of plants. The elements necessary for feeding plants of the present era were in the primitive rocks, but they underwent preparation before they were administered as food. If a child became rickety for the want of phosphate of lime in its food, no one would think of feeding it with crystals of Apatite phosphate of lime; or if a lady became bilious for want of soda in her system, what doctor would administer lumps of felspar? It was the same with plants: it is of no use to administer the constituents they require in a form they cannot digest. In the first place, the farmer must take care that he has food for his plants in the soil; and in the second place he must take care that they get at the food. Now, most soils contained many of the constituents required by plants in the rocks of which the earth was composed; but then these rocks required preparing; and how was this to be done? It was by *ploughing* and by *subsoil-ploughing*. Practice had suggested this, and science pronounced that it could not be dispensed with. By ploughing, the soil was reduced to powder, and the potash, the soda, and the lime had access to the carbonic acid and oxygen and water of the atmosphere, by which the important changes before referred to were produced. By ploughing, also, the soil became absorbent. It took into its very interior, where the roots of plants were seeking their food, the carbonic acid, the ammonia, and the water, which were the principal organic constituents of plants. In such a soil and with such agents did God grow the first forests of the world, and in such a manner must man act in order to grow the plants which he needs. The lecturer then went into calculations to show the enormous quantities of silicate of potash and soda contained in felspathic rocks, clay, slate, and loam, to show that where these rocks existed there could never be a deficiency of these agents. There was, however, a danger of ploughing up such soils too much; silicate of potash entered into the composition of the stems; it was phosphate of lime that entered into the seeds as well as the stems. Now, if the stems of plants were made to grow too luxuriously, by the aid of the silicate of potash, they would arrest the phosphate of lime going to the seed, and thus would do injury. The phosphate of lime existing in much smaller quantities in most soils, needed more frequently artificially renewing than the silicates. These were added in the form of guano, bone-dust, &c. In conclusion, he would add a few words on draining. When water was allowed to accumulate in a soil, it prevented the access of air, and thus prevented the action of the oxygen and carbonic acid on the ingredients of the soil. Water also dissolves up and carries off the most important constituents of a soil, and thus renders the land poor. Plants also require a certain temperature, and water, by its great absorption of heat during the process of vaporisation which was constantly going on, was a constant means of reducing the temperature of the soil. As a proof of the influence of the temperature of the soil on the development of plants, he pointed out that in low and heavy, and undrained districts, the harvest was always more backward than in high districts with a natural drainage, although the average temperature of the former districts was much higher. Whole counties in this country were badly drained; and he gave Cheshire as an illustration. This county was so badly drained, that it was said it was unfit for sheep to live in; he would only add, if it was unfit for sheep it certainly was unfit for man. This was an important consideration, that draining, which provided for a larger supply of food for man, also provided for the existence of man to consume the food. He illustrated the importance of drainage by relating a fact which had been communicated to him by Professor Liebig. Near Giessen is a prison from which dead bodies are supplied to the University for anatomical purposes. At one time it was very unhealthy, and a large number of deaths occurred, but the public authorities had lately had the district drained in which it was situated, and since that period the deaths in the place had been so few, that the University was now obliged to send to other places to supply its anatomical wants.

The Marquis of Downshire hoped that the Lecture which had just been delivered would be published, and proposed a vote of thanks to Dr. Playfair.—Lord Ebrington seconded the motion, and made some remarks on the geological view which the Lecturer had taken of the science of agriculture, and expressed the value of its importance.

The Chairman stated that the Lecture would be published in the Journal of the Society, and proposed a vote of thanks to the Governors of the Royal Institution for their kindness in allowing the use of their commodious theatre for the Lecture of the Society.

DR. PLAYFAIR'S SECOND LECTURE.

The Lecturer commenced by stating, that in his last Lecture he had endeavoured to demonstrate that the sequence of events from the first dawn of creation was calculated to elucidate the theory of the practice of agriculture. It was seen how carefully Nature had prepared her soils for cultivation, long before man had devoted himself to her service. He had showed how the ocean had acted as a great *plough* and *subsoil-plough*, and assimilated the noxious ingredients in the rocks, and made those which were fertile for the purposes of vegetation. How curiously she locked up in the soil those treasures of fertility, and the manner in which she presented the key to the industry of man, and showed him, by her own example, wisely reduced in energy from the past, when she herself had to clothe her own lands with vegetation, without man's aid. Still, though she reduced in intensity the causes formerly in operation, she preserved them in store for action, if that became necessary; and instances were seen in the operations of subsoil-ploughing and draining, in which she proved no niggard, when these causes were called into activity. We followed Nature also in those high and bleak regions of calcareous and cretaceous rocks, and then of the old red sandstone, in which she compensated for their elevation by an admirable system of drainage, either by causing numerous clefts or a porous nature of materials, so that the water might be quickly draughted away, and not by its evaporation render the soil cold; and, in this manner, how she pointed out to the farmer how best to improve the climate of his own district, how to increase as well as hasten the amount of vegetation, and the best way of making the capability of the soil available, and of obtaining the quickest return for the labour which was expended in its cultivation. In the present Lecture he should endeavour to apply the principles deduced from the observation of Nature, on a large scale, to the practice of the farmer, on a small one; and he believed that every one who neglected the study of these principles, would ever after have much reason to regret that he had not consulted the wishes and become acquainted with the elevated character of his great mistress. In the last Lecture, the importance of ploughing and draining had been insisted on; and this involved the explanation of fallow—the exposure of the constituents of the soil to the atmosphere. But although a soil is exhausted, for instance, of silicate of potash, so that Wheat would not grow, it did not follow necessarily that no other crop would grow, as there might still be plants that would grow with the remaining constituents of the soil. This subject was one of importance, as, if there were such crops, it would obviously present the necessity of a naked fallow. Professor Low, in his Agriculture, had recommended that soils be ploughed six or eight times; and this was a great waste of time and money, if nothing else could be grown in the interim. But in Scotland, in many parts of England, and in Jersey, such a system was now entirely dispensed with, and the theory of such a practice is easily understood by referring to what has recently been ascertained with respect to the composition of the mineral ingredients of plants. In the last Lecture a table was exhibited showing the principal mineral ingredients of plants, and although all plants contained these, they existed in very variable proportions, as the following table would show; and Liebig had even divided plants into classes, according to their mineral constituents:—

	Salts of Potash and Soda.	Salts of Lime and Magnesia.	Silica.
Silica Plants.			
Oat-straw, with seeds	34.00	4.00	62.00
Wheat-straw	22.00	7.20	61.05
Barley-straw, with seeds	19.00	25.70	55.03
Rye-straw	18.65	16.52	63.89
Lime Plants.			
Tobacco	24.34	67.44	8.30
Pea-straw	27.82	63.74	7.81
Potato-haulm	4.20	59.40	36.40
Meadow Clover	39.20	56.00	4.90
Forest Plants.			
Maize-straw	71.00	6.50	18.00
Turnips	81.60	18.40	—
Beetroot	88.00	12.00	—
Potatoes (tubers)	85.81	14.19	—
Helianthus tuberosus	84.82	15.70	—

This Table is only an approximation to the truth, and its classification inadmissible, as it was opposed to a beautiful law, pointed out by Liebig himself, and confirmed by the experiments of Will and Fresenius, which was that certain bases may replace each other, according to the law of equivalents. Thus, soda may be substituted for potash, and *vice versâ*; lime for magnesia, and so on; but it did not appear that an alkali could be substituted for an earth; still the Table was practically useful. The *rotation* of crops must depend on the character of the soil, and this would be seen by observing what kind of plants grew on the rocks mentioned in the last Lecture. On the granite rocks, the soil of which contained abundance of silicate of potash, the farmer grew mostly the silica plants, as Wheat, Barley, and Oats, after taking care to manure well with lime or bone-shells, to supply the absent calcareous matter and phosphates. It is seldom that such soils are devoted to pasture, or in other words, to the growth of lime plants. Clay, slate, and grauwacke are degraded granite, but deficient in lime and phosphates; for animals had not yet been formed, and their great characteristic was the possession of potash; and two potash plants, Oats, and Turnips, were most frequently cultivated on these soils, both of them requiring little of the phosphates and none of lime; on the sandstones, which were much richer in lime and phosphates, but still possessing potash, so that potash plants, and in addition, Wheat, Barley, and Clover, are grown on these soils. Above the sandstones we come to rocks abounding with animal and vegetable remains, and containing little potash; these rocks are not adapted for Wheat, Barley, Oats, or Turnips, and the lime-plants forming pastures are mostly grown. On the coal measures vegetation is poor, arising from the enormous exhaustion of the soil, produced by the plants forming the coal-beds; the clays, however, contained silicates and iron, and with care were cultivated so as to produce various crops. On the magnesian limestone plants were grown which required magnesia, and Potatoes, Wheat, and Barley flourished on these soils. After this we come to the new red sandstone, a soil composed of the detritus of former rocks, and capable of supporting potash, soda, and silica plants. The calcareous soils of the lias, the oolite, and the chalk yield lime-plants, Beans, Peas, Clover, and Barley. In examining the various kinds of rotations, it would be found that they were precisely such as were adapted to the soils in which they took place. Thus the Norfolk course begins with Turnips well manured, succeeded by a corn crop, followed by artificial Grasses, and concluded by another crop of corn; and this took place on most of the inferior clays of England. The manure yielded phosphates, but neither these nor the silica were taken up by the Turnips, and the soil thus became prepared for the growth of the corn, as the only thing of importance removed from the soil by the Turnips was the potash; and, what was important, potash uncombined with silica. If sheep upon the Turnips, they return to the soil the potash contained in the Turnips, and also of phosphates. After the second or corn crop has exhausted the soluble silicates and phosphates, a green crop is then grown, and this takes up the lime. By the time the lime is taken up by this crop, the action of the air upon the soil has liberated a further quantity of phosphates and silicates sufficient to grow for a fourth crop corn, which is often Barley, where lime is present, or Oats, or Wheat where it is deficient. Where there is magnesia present, as on the magnesian limestone, Potatoes may be substituted with advantage for the green crop, especially as their stems return to the soil the silicates. The curious rotation of the lower lias, consisting of Wheat, Beans, fallow, Oats, and Potatoes, would, in the same way be found adapted to the particular composition and characters of the soil on which it was practised. Enough had probably been said to show the farmer that rotation was not a means of *improving* the soil. The soil remained in the same state, as far as the plant was concerned, and the great advantage of it consisted in the fact that one crop could be grown whilst the soil was preparing for another. The theory of De Candolle, with regard to plants throwing out excrementitious matter injurious to themselves and beneficial to other plants, was now generally exploded, and many facts were entirely opposed to it. Thus, in Hungary, there was never a poisonous effect produced on the Wheat crops, although in some districts Wheat had been grown in succession for centuries. A like result to that of rotation is produced by many other processes on farms; take, for instance, burning and paring. By this process injurious organic matter is consumed. Plastic clays are quite changed in their character, not only by having all their constituents brought into contact with the oxygen of the atmosphere, and thus undergo change, but the clay itself acquires another character, it becomes absorbent, and takes up from the atmosphere ammonia, carbonic acid, and watery vapour, as well as afford more ready access to the nutritious substances which may be dissolved in water. But in this, you see nothing is destroyed, and the inorganic elements of the soil are only brought more fully into contact with the absorbing organs of the plants. Another process of the farm was what was called liming. When the chemist, in his laboratory, wished to dissolve up potash and silica from the soil he was examining, he used lime; and by this means he rendered soluble that which was insoluble before. Just what the chemist did in his laboratory by the use of lime, the farmer did in his fields; and this was the use of lime, that it rendered certain important ingredients of the soil more soluble than they were by nature. In this way, lime became a key by which the ingredients in the soil were unlocked; it did not in itself become an important ingredient in the soil. It may, however, happen that where we add lime, we may not only be using a means for unlocking the ingredients of the soil, but we may also be adding an important constituent of the soil. This was what made lime an important ingredient as a top-dressing where Clover and Grasses were to be grown. It would be seen, then, that lime was not used principally as a *manure*; it was seldom required as a manure, for a manure added to the composition of the soil; its principal use was as a solvent of other materials. Common salt was sometimes used as a manure, and Liebig supposed that it acted beneficially by combining with sulphate of lime, and a sulphate of soda was produced. If this was the case, it should act most beneficially on the cereals, and on the leguminous plants because they are the great generators of the constituents

of blood, gluten, albumen, and casein, and these are the parts of plants for which sulphur is absolutely necessary. He was not aware that this was the case. In connection with chloride of sodium he might say, that in a former part of the Lecture he had alluded to the fact, that soda might be substituted for potash in plants, and *vice versâ*, but this was no proof that potash could be substituted for soda in the system of the animal. Now it was found that soda was essential to the formation of healthy bile, and when animals were fed on potash plants in the centre of this island, or far away from the sea in continents, they sought with avidity soda in the form of common salt, for the purpose of adding this essential constituent to the elements out of which their secretions were formed. Another process which did not act in the way of direct manures was *irrigation*—the application of water to the soil. When fresh water was applied to the soil it was beneficial, but it was necessary, in order to insure its success, that the soil should be drained, as it was only fresh water was beneficial. Liebig accounted for this first by the oxygen contained in the water; when the oxygen came in contact with the soil it united with its constituents, and thus assisted in the process of disintegration. Another valuable property of the oxygen was that it united with the blue or protoxide of iron, and converted it into the peroxide; in the soils where this was contained, he had pointed out in the first Lecture the importance of this action. Again, other waters contained carbonic acid, and where this was the case in limestone districts, the water also held in solution carbonate of lime. Now the carbonic acid acted also on the constituents of the soil, and produced disintegration; and whilst this process went on, the carbonate of lime also, which it held in solution, was deposited on the soil as a manure. Stagnant waters, unless they contained uninjurious organic matters, were not beneficial to the soil, and when they became so they acted as true manures. He now came to the *true manures*. These matters supplied some substance that was destitute in the soil. The food animals got from plants consisted first of those secretions, containing large quantities of carbon, as sugar, starch, gum, &c., and those secretions which contained nitrogen. Now, although these secretions contained principally carbon, hydrogen, oxygen, and nitrogen, yet they required for their development inorganic matters. Thus Liebig had proved, that the carbonaceous secretions could not be developed in plants without the presence of small quantities of potash, phosphate of lime, &c. It was the same with the nitrogenised secretions. The forms of protein, albumen, fibrin, &c., required for their development phosphorus and sulphur, and these were obtained from the inorganic constituents of the soil. An important fact connected with the action of inorganic manures was, that none of these substances were destroyed in the system of adult animals—they were not destroyed as the carbonaceous and nitrogenous secretions, but were always again restored to the soil, in the form of excrementitious matter. It was thus that all animals, in their fæces and urine, returned to the soil those inorganic ingredients which they had taken up from the soil in their food. The Lecturer here went into a series of calculations, showing the necessity of using human excrement as manure. Where man ate Wheat, he threw off from his system those inorganic ingredients which were necessary to the growth of Wheat; where he ate Potatoes he furnished material for the growth of Potatoes. He proved these positions by reference to many well-conducted experiments on the composition of human excretions, from which it was found that they alone were capable, when properly preserved, of supplying all the exhaustion of the soil produced by the growth of food for man. These excretions varied in their composition, but it would be found they only varied according to the food which had been used. He urged upon all present the necessity of every means being used to make available this precious storehouse of inorganic matters for manuring, which not only existed in the right quantity as a food for plants, but also existed in the best form for the nutrition of the plants most needed by man. The value of the waste of these materials that was constantly going on was quite prodigious, and could only be estimated by those who looked upon the subject with a scientific eye. As some questions had been put to him since he had been in London, he would refer, before concluding his Lecture, to some remarks and experiments which had been made by M. Boussingault, the most distinguished agricultural chemist in France. This learned chemist had lately referred to some experiments of his own, with regard to feeding cattle. The French chemists had all along maintained that the fat of animals was only obtained from the fatty matter which they already took in with their food. On the other hand, the German chemists and himself maintained that the fat of animals arose from an imperfectly consumed form of the carbonaceous secretions, such as starch, sugar, and gum. A familiar instance of such a change took place in the burning of coal; when this substance was burned in the open air the whole of the carbon of the coal was consumed and carbonic acid was formed, but when coal was burned in closed vessels without access of oxygen, then a tarry matter was formed from the imperfect combustion. What took place in the coal took place in the starch, sugar, &c. Now, when animals have small lungs, these substances cannot be fully consumed by the want of oxygen, and an imperfect metamorphosis takes place—they are converted into oily matter, which is deposited in the form of fat. Dr. Lankester had pointed out this fact, in connection with a series of tables, drawn up by Mr. Hutchinson, of measurements and weights of human beings, in which it was found that in proportion to the circumference of the chest was the weight of the individual. He had, in previous Lectures before this Society, pointed out the fact that the broadest chested animals had the smallest lungs, and there could be little doubt that the smallness of the lungs taking up less oxygen in the human being accounted for the increased weight observed by Dr. Lankester. With regard to the experiment which M. Boussingault had criticised, and which he had characterised as having been performed "*avec une telle activité*," he could only say that he had stated at the time they were performed, they were to be taken only for what they were worth, from the short time in which they were performed, and as indications of experiments, with the same object in view. M. Boussingault had performed experiments to prove that he had been wrong in his conclusions, and he would allude to these experiments with that respect which was due to so distinguished a chemist. M. Boussingault, in order to prove that the fat of animals was not derived from the starch, sugar, &c., weighed animals before and after feeding with Mangold Wurzel and Potatoes (substances which contain very little fatty matter), and found that, instead of increasing in weight they diminished; and not only did they not diminish in weight in proportion to the less quantity of fatty matter they had been supposed to consume, but they diminished 100 lbs. in addition. Now, M. Boussingault had not considered the causes of this extra diminution of weight—a diminution so much greater than his theory required. But what were the real causes? Why, the cow had been fed on food which was unnatural to it; formerly it had been fed on hay, and other materials, which required the powers of its four stomachs to digest, but now it was given a food which it could not digest without bulk to assist the peristaltic action of its stomachs, and the consequence was, as every farmer knows, the animal was purged. Now, it was this purging that must have reduced its bulk, and not any want of the conversion of sugar and starch into fatty matter. These experiments of M. Boussingault did not prove that he was right, and they did not prove that he (Dr. P.) was wrong; at the best the experiments remained where he had placed his own at first, as among subjects that required further examination.

At the end of the Lecture, which occupied two hours in the delivery, P. Pusey, Esq., M.P., arose and said that Dr. Playfair had alluded to the debtor and creditor account of the farm, and he felt that the Society was deeply his debtor. He felt quite sure that the relation of science to practice, established in these Lectures, would be beneficial in causing more attention to the subject, and he had much pleasure in proposing a vote of thanks to Dr. Playfair. Earl Spencer seconded the motion. The first was an important Lecture, as embracing the scientific part of the question, and he considered this Lecture doubly important as applying that scientific part to practice. He particularly alluded to the portion of the Lecture with regard to manures, which he considered of great importance in establishing a relation between practice and science, which would lead to most beneficial results. Dr. Playfair had formerly given Lectures which had been productive of much practical benefit, and he was sure these would lead to the same result.

The Duke of Richmond put the motion, which was passed with acclamation. As President of the Society he felt indebted to Dr. Playfair for the ready manner in which he had responded to the hasty call of the Society, without throwing any difficulties in the way.

The Marquis of Downshire expressed himself as indebted to the Governors of the Royal Institution, for having afforded them the opportunity of hearing these Lectures in their theatre, and proposed a vote of thanks. The Earl of Essex seconded the motion.

ROYAL AGRICULTURAL IMPROVEMENT SOCIETY OF IRELAND.

At the half-yearly meeting of this Society, held on Friday last, the half-yearly Report for the current year was read, from which we make the following extracts:—

"At the close of the year 1843 the number of members who had paid in their subscriptions amounted only to 500, whilst 945 have paid their subscriptions for the current year. This gratifying fact may be attributed in some measure to the rule which was adopted at the last general meeting, namely, requiring that to entitle a local farming Society to the premiums of the central Society the members of it shall contribute a certain proportion to the funds of the central Society. The propriety of this regulation was much questioned at the time, but its adoption has proved most beneficial, not only in the increase of members, but from the greater interest in the affairs of the Society which it has caused. Of the 100 local Societies at the commencement of this year, in connection with the central body, only 16 have failed to avail themselves of the provisions of the rule referred to; while in those which have so qualified, the competition for the different premiums has been much increased, and the prizes themselves claimed to a much greater amount than in previous years. The second source of increased revenue to the Society, during the present year, was its great annual Cattle Show, held in the city of Dublin on the 14th and 15th of August last, on which occasion upwards of 200 new members were also added, making a total of 450 new members in one year. The number of subscribers is still, however, very disproportionate to that of the landed proprietors of Ireland; yet your council deem it a source of gratulation to find such a steady and progressive increase to the Society, and they feel that the addition may be fairly considered the best possible proof of the favour with which the operations of the Society are now regarded by the public. When the council consider the many advantages to the country at large from the great Cattle Show in Dublin—the vast numbers which attended from all quarters on the occasion, and the success of the different entertainments incident to the Show, they have every reason to be satisfied with the result of the meeting. The number of entries to the show-yard was greater than on any former occasion, as appears by the following return, viz.:—

Short-horned bulls		46
Devon	do.	18
Long-horned	do.	4
Hereford	do.	4
Ayrshire	do.	4
Polled Angus	do.	5
West Highland and Kerry	do.	4
Extra stock.		10
	Total number of bulls	92
Cows and heifers, general competition		39
Ditto, local competition		132
Extra stock		16
		187
Fat stock		15
Horses, mares, colts and fillies		74
Extra stock		11
		85
Sheep		68
Swine		52
Total number of entries		499

The council have also observed with satisfaction that in most cases the prizes were carried away by animals bred and reared in this country, and therefore recommend that in future the distinction between local and general competition shall be abolished, and that all the premiums should be open to general competition. The advantage of this arrangement, they trust, will soon be felt in stimulating local breeders to increased exertion, and introducing animals into this country. The exhibition of implements was the largest and most varied that has yet appeared under the auspices of the Society—many most valuable and well-arranged lots having been sent from England and Scotland, while the different exhibitors in this country showed the greatest anxiety to forward the objects of the Society by contributing largely upon the occasion. The council, therefore, recommend that the premiums for implements at the next Show should be increased considerably, and classified like the other prizes. The exhibition of flax, wool, and butter, was not so extensive as might have been desired, but the council are so satisfied of the necessity of calling public attention to the improved manufacture of these several important articles, that they strongly recommend a continuation of the premiums for them at the Show for the ensuing year. Your council have also turned their attention, during the present year, in some measure to the distribution of practical and useful knowledge among the farming classes; and for this purpose have caused a second edition of the Society's Transactions to be published for circulation, and have appointed Messrs. Curry and Company, of Dublin, publishers to the Society for Ireland: Messrs. Longman and Company, of London, for England; and Messrs. Frazer and Company, of Edinburgh, for Scotland. This, the Society's first volume of Transactions, contains, exclusive of the ordinary proceedings of the Society, much useful and valuable information, particularly on the subject of thorough-draining and reclaiming waste land in Ireland, which they feel they can confidently recommend to the members of the Society and the public at large. The balance-sheet of the late Cattle Show, held in this city, was next laid before the meeting. The following is a correct account of the receipts and expenditure on that occasion:—

Balance Sheet of Cattle Show in Dublin.

Expenses.	£.	s.	d.
By amount of expenditure in Show-yard	288	11	9
Ditto Council Dinner, Rotunda	328	10	9
Ditto, Banquet Dinner, Theatre	435	19	11
Ditto Ball, Theatre Royal	493	9	0
By sundries, including Printing, Stationery, Advertisements, Staff-Assistants, &c.	331	8	7
Premiums awarded at Cattle Show	664	0	0
Medals ditto	67	1	10
Extra	0	0	0
	£3109	7	10
Receipts.			
To amount of receipts on foot of Show-yard	778	13	6
To ditto on foot of Council Dinner	327	12	0
To ditto on foot of Banquet Dinner	324	0	6
To ditto on foot of Ball	445	9	6
Local Fund	261	11	0
Premiums unpaid	55	0	0
Extra	0	1	0
	2987	6	6
Balance	312	1	4
	£3109	7	10

The secretary here stated, that although the amount of balance against the Society might appear large at first view, yet, in consequence of the demonstration made by them, there had been an addition of 450 new members, which was mainly attributable to the Society having made those demonstrations by which the expense had been incurred; and that, taking this fact into account, there would be altogether a balance of 16*l.* 7*s.* in favour of the Society. It was then resolved, "That the next Cattle Show be held at Ballinasloe, on Tuesday, the 30th of September next, and continue for three days." The Marquis of Downshire then rose to say that chemistry was making its way in England amongst the agriculturists, and he hoped to see it advancing equally in this country. He had, therefore, suggested to Mr. Bellen, the secretary to the Society, that one or more chemists should be solicited in each town in Ireland, who should be requested to name their price as to the analysis of earths, manures, &c., whenever they should be applied to by gentlemen or farmers on the subject. His attention had been first drawn to the subject by his having been applied to to become a subscriber to the new College of Chemistry

object to be established in London. He had felt great pleasure in contributing to so excellent an institution; and he could name several noblemen and gentlemen, among them the Duke of Wellington and Lord Dudley, who were to be found among its supporters. His present suggestion was merely thrown out as a preliminary step for a similar institution in this country, and he thought the proposal worthy of the serious consideration of the Society.

FLAX SOCIETY OF IRELAND.

At the Monthly Meeting of the Committee, the following letter was read from Mr. Northcote, written by order of the Right Honourable W. E. Gladstone, President of the Board of Trade:—"Whitehall, Nov. 16, 1844. Sir,—I am directed by Mr. W. E. Gladstone, to acknowledge the receipt of your communication, of the 12th instant; and to thank you for your information respecting the increased growth of Flax in Ireland. The quantity of foreign Flax imported, in the year ended the 5th January, 1844, was 1,437,150 cwts.; of which 1,422,992 cwts. were entered for consumption. The quantity imported, this year, up to the 10th October, was 1,129,173 cwts.; and the quantity entered for consumption, in the same period, was 1,129,536 cwts. I am, sir, your obedient servant, STAFFORD H. NORTHCOTE.—James Mac Adam, Esq."

SMITHFIELD CLUB.

THE EXHIBITION OF FAT CATTLE, for the Premiums offered by this Society, took place during the past week at the Horse Bazaar, Baker-street. The following is the award of the Judges:—

OXEN.

CLASS I.—*Oxen or Steers, of any Breed, under 5 years old, without restrictions as to feeding; yet the kind or kinds of food must be certified.*

To Mr. ROBERT SMITH, of Burley-on-the-Hill, near Oakham, Rutland, for a 3 years and 11½ months old improved Short-horn Steer, bred by himself, and fed on Oil-cake, Barley, and Bean-meal, vegetables, and Hay; travelled to the Show, by van, 20 miles, and by railway 100 miles—*Prize*, 20*l.*, and *Silver Medal* to the breeder.

To Mr. JOHN HUDSON, of Castle Acre, near Swaffham, Norfolk, for his 3 years and 10 months old Hereford Ox, bred by Mr. John Longmore, of Orlton, near Leominster, and fed on Grass, Hay, Swedes, Linseed-cake, and Mangold Wurzel. Travelled to the Show by van 100 miles—*Prize* 10*l.*

To Mr. T. L. MEIGE, of Cound Arbor, near Shrewsbury, Shropshire, for his 3 years and 11 months old Hereford Ox, bred by himself, and fed on Cake, Pea, and Barley-meal, boiled Barley, Grains, Grass, Hay, Turnips, and Mangold Wurzel. Travelled to the Show on foot 2 miles, by van 7 miles, by canal-boat 50 miles, by railway 100 miles—*Prize* 10*l.*

HIGHLY COMMENDED:

Mr. R. M. LAWSON, of Thorney Abbey, near Peterborough, Northamptonshire, for his 4 years and 6 months old Hereford Bullock, bred by Mr. John Turner, of Stoke, near Leominster, Herefordshire, and fed on Hay, Linseed-cake, Bean-meal, Carrots, and Swedish Turnips. Travelled to the Show by van 54 miles, and by railway 67 miles.

Mr. RICHARD MEIGE, of Cound, near Shrewsbury, Shropshire, for his 4 years old Hereford Ox, bred by Mr. T. L. Meige, of Cound, and fed on Oil-cake, Barley, and Pea-meal, boiled Barley, Grains, Grass, Hay, Turnips, and Mangold Wurzel. Travelled to the Show on foot 2 miles, by van 7 miles, by canal-boat 50 miles, and by railway 100 miles.

Mr. WILLIAM TRINDER, of Wantage, Berkshire, for his 3 years and 5 months old Hereford Steer, bred by Mr. William Hewer, of Northleach, Gloucestershire, and fed on Grass, Hay, Turnips, Mangold Wurzel, Carrots, Meal, and Oil-cake. Travelled to the Show on foot 2 miles, and by van 80 miles.

CLASS II.—*Oxen or Steers of any breed, under 6 years old, weight 90 stone and upwards, that shall not have had Cake, Corn, Meal, Seeds, Grains, or Distillers' Wash, during 12 months previous to the 1st of August*, 1844.

To Mr. JAMES BULT, of Kingston, near Taunton, Somerset, for his 4 years and 10 months old Short-horned Steer, bred by himself, and fed on Hay, Grass, Swedish Turnips 300 lbs. of Flax-seed, 5 bushels of Peas, 11 bushels of Barley, and 9 bushels of Beans. Travelled to the Show on foot 5 miles, and by railway 163 miles—*Prize* 30*l.* and *Silver Medal* to the Breeder.

To Sir JOHN HENRY PALMER, Bart., of Carlton, near Rockingham, Northampton, for his 4 years and 2 months old Durham Ox, bred by himself, and fed on Grass, Hay, Turnips, Carrots, Mangold Wurzel, Cabbage, 1545 lbs. of Oil-cake, and 435 lbs. of Bean-meal. Travelled to the Show by van 25 miles, and by railway 60 miles—*Prize* 10*l.*

CLASS III.—*Oxen or Steers, of any breed, under 5 years old, under 100 stone and above 70 stone weight, that shall not have had Cake, Corn, Meal, Seeds, Grains, or Distiller's Wash during 12 months previous to the 1st of August*, 1844.

To His Grace the DUKE OF BEDFORD, of Park Farm, near Woburn, Beds, for a 4 years old Hereford Ox, bred by his Grace, and fed on Grass, green Tares, Hay, Turnips, 500 lbs. of Linseed-meal, and 500 lbs. of Barley-meal. Travelled to the Show by van 42 miles—*Prize* 15*l.* and *Silver Medal* to the Breeder.

To Mr. H. CHAMBERLAIN, of Desford, near Leicester, for his 4 years and 10 months old Hereford Ox, bred by himself, and fed on Grass, Hay, Green Vetches, Turnips, 910 lbs. of Cake, and 695 lbs. of Pea-meal. Travelled to the Show on foot 10 miles, by railway 107 miles.—*Prize* 10*l.*

Highly commended.—The Right Hon. EARL SPENCER, of Althorp Park, near Northampton, for a 4 years and 5 months old Durham Ox, bred by his Lordship, and fed on Mangold Wurzel, Turnips, Cabbages, Hay, and 1452 lbs. of Cake. Travelled to the Show by van 10 miles, and by railway 60 miles.

CLASS IV.—*Oxen or Steers, of any breed not exceeding 4 years and 3 months old, and under 80 stone weight, that shall not have had Cake, Corn, Meal, Seeds, Grains, or Distiller's Wash, during 12 months previous to the 1st of August*, 1844.

To his Grace the DUKE OF BEDFORD, of Park Farm, near Woburn, for a 3 years and 9 months old Hereford Ox, bred by his Grace, and fed on Grass, Green Tares, Hay, Turnips, 500 lbs. of Barley-meal, and 500 lbs. of Linseed-meal. Travelled to the Show on foot three miles, by van 6 miles, and by railway 41 miles—*Prize* 10*l.*, and *Silver Medal* to the Breeder.

To Mr. JOHN MANNING, of Harpole, near Northampton, for a 3 years and 10 months old Hereford Ox, bred by Mr. James Williams, of Culmington, near Ludlow, and fed on Grass, Hay, 850 lbs. of Cake, and 4 bushels of Bean-meal. Travelled to the Show on foot 7 miles, and by railway 69½ miles—*Prize* 5*l.*

Highly commended.—The Right Hon. LORD SOUTHAMPTON, of Whittlebury, near Towcester, Northamptonshire, for a 3 years and 9 months old Hereford Ox, bred by Mr. F. Corton, of Hayton, near Ludlow, and fed on Corn, Hay, Chaff, Tares, Turnips, 1050 lbs. of Cake, 17 bushels of Oats, and 120 lbs. of Barley and Bean-meal. Travelled to the Show on foot 8 miles, and by railway 60 miles.

CLASS V.—*Oxen or Steers, of any breed, under 4 years and 6 months old, and under 80 stone weight, without restrictions as to feeding, yet the kind or kinds of food must be specified.*

To Mr. W. J. BAILEY, of Shenley House, Stoney Stratford, Bucks, for a 3 years and 8 months old Hereford Steer, bred by Mr. W. Wheeler, of Ivington Park, near Leominster, and fed on Grass, Hay, and Cake. Travelled to the Show on foot 8 miles, and by railway 50 miles—*Prize* 10*l.*, and *Silver Medal* to the Breeder.

COWS AND HEIFERS.

CLASS VI.—*Fattened Cows or Heifers under 5 years old. Freemartins and Spayed Heifers are not qualified.*

To Mr. HENRY BROWN, of Ashby-de-la-Zouch, Leicestershire, for a 4 years and 6 months old Durham Heifer, bred by himself, and fed on Oil-cake, Barley, Grass, Cabbage, Swedish Turnip, and Hay. Travelled to the Show by van 25 miles, and by railway 96 miles—*Prize* 20*l.* and *Silver Medal* to the Breeder, and *Gold Medal* as the best Beast in any of the Classes.

To the Right Hon. EARL SPENCER, of Wiseton, near Bawtry, Nottinghamshire, for a 4 years and 5 months old Short-horned Cow, bred by his Lordship, and fed on Hay, Turnips, Cabbages, Pea-meal, Barley-meal, and Oil-cake. Travelled to the Show by van 20 miles, and by railway, 172 miles—*Prize* 10*l.*

To Sir THOMAS WHICHCOTE, Bart., of Aswarby Park, near Folkingham, Lincolnshire, for a 4 years and 5 months old Durham Heifer, bred by himself, and fed on Linseed-cakes, Bean-meal, Oat-meal, Hay, and Vegetables. Travelled to the Show by van 38 miles, and by railway 107 miles—*Prize* 5*l.*

CLASS VII.—*Fattened Cows or Heifers, of 5 years old and upwards. Freemartins and Spayed Heifers are not qualified.*

To Mr. JOHN BEASLEY, of Chapel Brampton, near Northampton, for 5 years and 4 months old short-horned Cow, bred by himself, and fed on Grass, Turnips, Mangold Wurzel, Hay, Linseed-cake, and Oat-meal. Travelled to the Show by van 9 miles, and by railway 60 miles—*Prize* 20*l.* and *Silver Medal* to the Breeder.

To Mr. JOHN CARWARDINE, of Marsh, near Leominster, for a 5 years and 11 months old Hereford Cow, bred by the late Mr. John Morris, of Stratford Bury, near Leominster, and fed on Grass and Oil-cake. Travelled to the Show on foot 48 miles, and by railway 113 miles—has had 1 calf—*Prize* 5*l.*

CLASS VIII.—*Fattened Cows, of 5 years old and upwards, that shall have had at least 2 live Calves at separate births.*

To Mr. J. S. BURGESS, of Holme Pierrepont, near Nottingham, for a 7 years and 5 months old Short-horned Cow, bred by Mr. Burgess, of Cotsgrove Place, Nottingham, and fed on Cake, Beans, Vegetables, and Hay. Travelled to the Show by van 5 miles, and by railway 126 miles—has had 3 calves—*Prize* 15*l.* and *Silver Medal* to the Breeder.

To Major BROWN, of Welbourn, near Grantham, Lincolnshire, for a 13 years old Short-horned Cow, bred by himself, and fed on Linseed-cakes, Swedes, Turnips, Hay, Clover, and Lucerne. Travelled to the Show by van 40 miles, and by railway 100 miles—has had 6 calves—*Prize* 5*l.*

Highly commended.—Mr. WILLIAM FIRTH, of Kirkstall, near Leeds, for a 9 years and 8 months old Short-horned Cow, bred by Mr. William Henlock, of Great Ouseburn, York, and fed on Oat-straw, Turnips, Oil-cake, Hay, Grass, and Clover. Travelled to the Show by van 4 miles, and by railway 196 miles—has had 4 calves.

EXTRA STOCK.—CATTLE.

Highly commended.—His ROYAL HIGHNESS PRINCE ALBERT, of Windsor Castle, a 5 years and 6 months old Pure Angus Polled Ox, bred by Mr. Hugh Watson, of Keillor, Forfarshire, and fed on Oil-cake, Oats, Beans, Hay, Swedes, and green food. Travelled to the Show by van 24 miles. [This was an extraordinarily large animal.]

SHEEP.

CLASS IX.—*Long-woolled fat Wether Sheep, 1 year old, that have never had Cake, Corn, Meal, Seeds, or Pulse.*

To Mr. J. S. BURGESS, of Holme Pierrepont, Nottinghamshire, for a pen of three 20 months old Long-woolled Wethers, bred by himself—*Prize* 20*l.* and *Silver Medal* to the Breeder.

To Mr. THOMAS TWITCHELL, of Wellington, near St. Neots, Beds., for a pen of three 20 months old Leicester Wethers, bred by himself, from rams hired of Mr. Samuel Bennett, of Birkeslags Park, near Woburn, Beds.—*Prize* 5*l.*

CLASS X.—*Long-woolled fat Wether Sheep, 1 year old, under 8 stone weight, that have never had Cake, Corn, Meal, Seeds, or Pulse.*

To Mr. J. S. BURGESS, of Holme Pierrepont, Nottinghamshire, for a pen of three 20 months old Long-woolled Wethers, bred by himself—*Prize* 10*l.* and *Silver Medal* to the Breeder.

CLASS XI.—*Long-woolled fat Wether Sheep, 1 year old, without restrictions as to feeding.*

To his Grace the DUKE OF BEDFORD, of Oakley West Farm, Bedford, for a pen of three 20 months old New Leicester Wethers, bred by his Grace—*Prize* 20*l.* and *Silver Medal* to the Breeder, and *Gold Medal* as the best pen of Long-woolled Sheep in Classes IX., X., and XI.

To Mr. JOHN PAINTER, of Burley, near Oakham, Rutland, for a pen of three 21 months old New Leicester Wethers, bred by himself, from a ram hired of Mr. Thorpe, of Clifton, Nottinghamshire—*Prize* 5*l.*

CLASS XII.—*Long and Short-woolled cross-bred fat Wether Sheep, 1 year old, without restrictions as to feeding.*

To Mr. C. TOMSON, of Sundon, near Luton, Beds., for a pen of three 21 months old Southdown and Gloucester Cross Wethers, bred by himself—*Prize* 10*l.* and *Silver Medal* to the Breeder.

To Mr. W. BENNETT, of Lewsey Farm, near Dunstable, Bedfordshire, for a pen of three 21 months old Down and Leicester Cross Wethers, bred by himself—*Prize* 5*l.*

EXTRA STOCK.—LONG WOOLLED SHEEP.

To Mr. C. LARGE, of Broadwell, Oxfordshire, for a 56 months old New Oxfordshire Ewe, bred by himself—*Silver Medal.*

CLASS XIII.—*Short-woolled fat Wether Sheep, 1 year old, without restrictions as to feeding.*

To Mr. SAMUEL WEBB, of Babraham, near Cambridge, for a pen of three 20 months old Southdown Wethers, bred by Mr. J. Webb, of Babraham—*Prize* 20*l.* and *Silver Medal* to the Breeder.

To His Grace the DUKE OF RICHMOND, of Goodwood, near Chichester, Sussex, for a pen of three 20 months old Southdown Wethers, bred by His Grace—*Prize* 5*l.*

CLASS XIV.—*Short-woolled fat Wether Sheep, 1 year old, under 8 stone weight, without restrictions as to feeding.*

To Mr. HENRY UPTON, of Oving, near Chichester, Sussex, for a pen of three 20 months old Southdown Wethers, bred by Mr. A. Pinnix—*Prize* 10*l.* and *Silver Medal* to the Breeder, and *Gold Medal* as the best pen of Short-woolled Sheep in Classes XIII. and XIV.

CLASS XV.—*Short-woolled fat Wether Sheep, 2 years old, without restrictions as to feeding.*

To Mr. E. G. BARNARD, M.P., of Gosfield Hall, near Halstead, Essex, for a pen of three 32 months old South Down Wethers, bred by himself—*Prize* 20*l.* and *Silver Medal* to the Breeder.

EXTRA STOCK.—SHORT-WOOLLED SHEEP.

To Mr. T. HARRIS, of Hinton, near Abingdon, Berkshire, for a 21 months old South Down Sheep, bred by himself—*Silver Medal.*

PIGS.

CLASS XVI.—*Pigs, of any breed, above 13 and under 26 weeks old.*

To Mr. W. F. HOBBS, of Marks Hall, near Kelvedon, Essex, for a pen of three 25 weeks and 4 days old Improved Essex Pigs, bred by himself, and fed on Oats, Peas, Meal, Potatoes, Mangold Wurzel, and milk—*Prize* 10*l.*, and *Silver Medal* to the Breeder.

To His ROYAL HIGHNESS PRINCE ALBERT, of Windsor Castle, for a pen of three 25 weeks and 4 days old Suffolk and Bedfordshire Pigs, bred by His Royal Highness, and fed on Milk, Barley-meal, and Pea-meal—*Prize* 5*l.*

CLASS XVII.—*Pigs, of any breed, above 26 and under 52 weeks old.*

To Mr. J. BUCKLEY, of Normanton Hill, near Loughborough, Nottinghamshire, for a pen of three 27 weeks and 2 days old Neapolitan and Warwickshire Pigs, bred by himself, and fed on Barley-flour—*Prize* 10*l.*, and *Silver Medal* to the Breeder.

To the Right Hon. the EARL OF RADNOR, of Coleshill, near Farringdon, Berks, for a pen of three 44 weeks and 1 day old Coleshill Pigs, bred by his Lordship, and fed on whey, Barley-meal, and Potatoes—*Prize* 5*l.*

EXTRA STOCK.—PIGS.

To Mr. W. F. HOBBS, of Marks Hall, near Kelvedon, Essex, for a 25 weeks and 4 days old improved Essex

Pig, bred by himself, and fed on Oats, Peas, Meal, Potatoes, Mangold Wurzel, and Milk.—*Silver Medal.*

It will be observed that His Royal Highness Prince Albert exhibited several animals, amongst which were Pigs to which a Prize of 5*l.* was awarded, and an Ox of the Polled Angus breed, which attracted considerable attention.

Besides the Show of Fat Cattle, which *alone* was originally established by the Smithfield Club, there has grown up of late years an Exhibition, in the same place, of Agricultural Implements; manufacturers no doubt finding it profitable to take advantage in this manner of these annual assemblages of farmers. There was not many new implements exhibited: the following reference to some of the articles shown may interest some of our readers:—The stand of Messrs. *J. Gibbs & Co.*, seedsmen to the English Agricultural Society, was the first that met the eye on entering. We noticed there enormous specimens of long red and globe yellow Mangold Wurzel, and also of Kohl Rabi. There was also some series of specimens of Grasses and Wheat on the stand. Specimens of all these were also exhibited by Messrs. G. Gibbs and Co. At another stand specimens of Swedish Turnips, weighing about 20 lbs., were exhibited; and Mr. Skirving exhibited heavy specimens of his well-known variety. Among the implements we noticed two applications of the lever-power to Hand-threshing Machines—a mode of working them which was first introduced by Messrs. Ransome, of Ipswich. In one—that by Mr. Cambridge, of Devizes—the oscillatory motion of the lever was converted into the rotatory motion of the drum of the implement, by means of sun-and-planet toothed wheels; in the other—a heavy and bulky machine, exhibited by Lieut. Viburt, R.N.—the crank was employed for this purpose, and the action of three levers worked by three men was brought to bear upon it. One of the cleverest implements in the gallery was a Horse-rake, exhibited by Mr. Smith, of Stamford, in which all the action of Mr. Grant's excellent and well-known implement is obtained in a very simple manner. We must postpone a description of this implement till another opportunity. Nothing new was observed among Drilling-machines: implements of this class were exhibited by Messrs. Hornsby, of Grantham, Garrett and Exall, and Smyth, of Ipswich. A variety of Cake and Corn-crushers was exhibited by the two first-named manufacturers; those of the former being distinguished by their peculiar make—the working cylinders being covered with pinnacle instead of ridge-formed teeth. Among Turnip-cutters we noticed an ingenious implement by Mr. Wedlake, in which the working cylinder cut slices or finger-shaped pieces according to the position of the hopper, and the direction in which the handle was turned. Another, exhibited by Messrs. Wedlake and Thompson, consisted of a horizontal revolving circular disc, on which the cutters were placed, and through which the slices fell as they were necessarily cut off the lower surfaces of the bulbs placed in a box above it. We must not forget mentioning Smith's Field-garden Hand-dibble, exhibited by Messrs. Cottam and Hallen. It was referred to some weeks ago in this Paper by a correspondent, and, though we have no experience of it, appears likely to answer its purpose. Its cost is 35*s.*

Besides the few we have mentioned, the usual variety of agricultural implements was exhibited by their respective manufacturers; and notwithstanding the absence of implements from the factory of the Messrs. Ransome, at Ipswich, which generally sends out so many, there appeared to be both number and variety sufficient in the Exhibition to interest the crowds that inspected it.

An intimation was given by Earl Spencer that it was the intention of His Royal Highness Prince Albert to honour the Club with a visit, but the day had not yet been fixed. It was, however, generally supposed that this morning (Saturday) would be the most likely time.

FARMERS' CLUBS.

Stowupney.—The twelfth Monthly Meeting of this Farmers' Club was held on the 2d inst. Mr. Maughan, of Dudley, read the following Essay on the Expediency of Leases. First, As to the objections against leases:—"I find some brought together by an annotator on 'Tuke's Survey of the North Riding of Yorkshire.' He observes, it is the popular fashion of the times to rail at tenancy from year to year—to assert that a country so held must be devoid of improvement, the tenantry oppressed, and the landowners deprived of that share of rent which they ought to receive were their lands let on what they call a more durable tenure. He observes that the permanency of tenure under lease is held to be one of the greatest inducements to cultivation; but he contends that, with tenants from year to year, occupation is more durable than with the former—that the occupations of the latter are rarely changed, except for faults; and so far as leases prevent such changes, they are evils. He alleges that few estates let to yearly tenants can be pointed out where the same families have not remained on them for many generations. He contends that where leases are common, the greater part of the tenants are changed at their expiration, for, no mutual tie, either of friendship, honour, or attachment, existing between landlord and tenant, the former is bound only by interest to the latter, and the latter, presuming upon the certainty of his lease, gives probably some occasion of offence, which is not forgiven when it expires. It is contended, too, that in cases of tenancy from year to year, rents are not so frequently advanced as on estates where leases are granted, and that both for permanency of occupation and moderation of rent, tenancy from year to year is most in favour of the tenant, and that, for such moderation, the landlord has an ample return in the attachment and good offices of his tenantry. Another objection, on behalf of the tenant, made to leases is, that if a rent be reserved fluctuating with the price of produce, the rent bears hardest on the tenant when he is least able to discharge it. Another objection to leases made on behalf of landlords is, that leases fairly granted on fixed money rents—I mean fairly granted with reference to circumstances existing at the time of the contract—often become, by a change of circumstances, altogether one-sided, and in favour of the tenant; for if the prices of produce advance, the landlord cannot share in the benefit; but if, on the other hand, prices fall, he is obliged to reduce the tenant's rent, to keep him (as the phrase goes) on his legs. Secondly, As regards the arguments advanced in favour of leases. It is said that no prudent tenant farmer will venture his money in the improvement of his land without security; that is to say, not an absolute certainty that the money expended will be returned to him, but certainty in the opportunity of conducting and of carrying out, in a series of years, that course of operations on which, at the commencement, his calculations were founded, and whereby alone he could hope to redeem his expenditure with compensation for the time bestowed, the labour imparted, and the hazards incurred in the enterprise. Another argument in favour of leases is derived from experience of their benefit in many parts of the kingdom, where they have been judiciously adopted. In connection with this subject it has been, perhaps not unjustly said, that in almost every field in the country there is an unworked, or an imperfectly worked mine of agricultural wealth, but that it cannot be brought to light without an expenditure of money, which, once sunk in the soil, can only be recovered in the course of years; and it is asked, Can the farmer who has his farm from year to year only, with justice to himself and his family, enter freely upon this outlay? The ordinary confidence reposed in landlords, and in the agents of landlords, will not overcome those prudential considerations; the thought that his security is not real, alarms the worldly prudence of the tenant, and banishes all idea of improvement or outlay. This is a fact of which we may convince ourselves by the evidence of our own eyes, that under a system of tenancy from year to year, the lands of this kingdom generally are cultivated imperfectly. There is good and spirited management by yearly tenants here and there to be met with, but it is the exception, and not the rule. In examining the arguments of writers upon leases, I have nowhere found so much said, and so well said, in their behalf, as in an article written by Mr. Hannam, of North Deighton, in Yorkshire. As I doubt whether it be possible to add much to his conceptions upon this subject, or to improve upon his manner of expressing them, I shall, with this willing acknowledgment, borrow freely from Mr. Hannam's paper. After speaking of the disadvantages with which the tenant farmer often has to contend—fickle seasons, fluctuating markets, insolvent customers, and other evils—he proceeds to remark, that greater than all those is the disadvantage arising from the uncertainty of the tenant being allowed to continue unmolested in his occupation, after his money shall have been embarked in improvements requiring more than that average outlay which is necessary for ordinary and routine management. Mr. Hannam observes that upon the system of yearly tenancy there are other attendant evils; one is the facility which it affords to men without skill or capital to obtain farms; and another, the temptation it holds out to the needy man to make a temporary convenience of a farm. Hence, we continually see tenants with a capital of 500*l.* upon a farm requiring 1000*l.*; for as the occupier is a tenant from year to year, there is not generally that investigation into his qualifications which there ought to be, and which there undoubtedly would be were a lease for a long term of years about to be granted; and on his side the tenant is often impelled to take hold of an engagement, though not to his mind exactly, as a convenience, and until he meets with something that suits him better. The result, he observes, of these contracts may easily be defined. If the farm be out of order at first, the tenant who takes it as a convenience (*i. e.* on the determination to get all he can from it without much cost), soon finds that it will not bear robbery; but he finds out also that it will not do to expend money on it; he is therefore content to take what it gives, and to return to it nothing; and he robs it, or it robs him, till after a time there is no more left to rob. In the other case, the tenant finds himself on a farm with a supply of cash below the demand, his farm requiring improving, but "it must be done bit by bit, he must see how it answers," are his cogitations; and of course—as under this sort of management it grows worse—his land goes half stocked, his crops fail, and he finds himself in difficulties before he knows how to turn himself; the capital he had is melted, and that without making any reform in the condition of his farm; and in a short time he is left penniless and in the possession of a farm which after such a course of negligent management requires a capital double of what it ought to do. So much, then, for the evils of the system, which the advocates of leases would abolish! The advantages of the one they recommend may be stated to be the prevention of those very evils which the other produces. They would endeavour to raise up a class of men possessing capital to expend, and they would give them confidence to expend it. It is not, however, as Mr. Hannam remarks, to be asserted that all tenants holding from year to year are bad managers; on the contrary, there are many, very many, first-rate farmers who are tenants merely from year to year. But then, as tenants it may be said their lines have fallen in lucky places, or they would not risk the outlay generally necessary to superior management. And even in these cases we may rest assured that those tenants who do much without the security of leases would do more, much more, if they possessed such security. They are, consequently, not such good farmers as they would be were they secure, for a series of years, under the stipulations of a lease. It will perhaps be urged that the farmer will, under a lease for 15 or 20 years, be too much affected by a depression of prices, unless his contract be a very advantageous one; and that, under such circumstances, he will not be able to procure any relief from his landlord. Now, it is true the tenant will not be able to say "You must reduce the rent of *my* farm, or I must leave it." There is, however, no reason to assume that this demand will be made. A contract which has to be in force for a length of time would be considerately made; it would be based upon the prices of products for a number of years preceding the contract. But when the holder of a lease takes a farm, he values the gross products of the same in its present condition. If, therefore, he can make it produce one-fourth more than it did formerly, his lease insures him the benefit of it, and encourages him to continue his improvements; and when a depression of the market takes place, if his produce does not fetch so much as it did once, he finds he has more in quantity, so that the aggregate value shows still in his favour; but, should brisk markets come, he has both good prices and an increased quantity of produce. I deem it too obvious to require to be argued that the rent reserved ought not to be a fixed money payment, but should fluctuate with the fluctuations in the prices of produce—in most cases with those of grain. By this means, the landlord and tenant are alike protected. But some will say that if this arrangement does good to the tenant at one time it does evil to him at another; for, since high prices are not only caused by increased consumption, but also by decreased production, when the price of grain rises, owing to a deficient yield, or to a bad harvest, the farmer will have to pay an increased rent. This may, in the opinion of some, be a weighty objection. But it really is not a weighty objection, when the subject is duly examined; for, if all the circumstances producing fluctuations in prices are considered, it will be found that the tenant holding under a lease, at a corn or other produce rent, will have three points out of four in his favour. I particularly invite attention to what Mr. Hannam so well says upon this branch of the subject. Take the case of a corn rent for the purpose of illustration. Thus, First—if prices are low from a limited demand, he has a reduction in rent. Second—If prices are low from increased production, he has more grain, yet, at the same time, a reduced rent. Third—If, on the other hand, prices are high from an increased demand, he has a higher rent to pay, but then he has more money to pay it with. Fourth—It is only when the advance of price arises from decreased production that it operates against him. Then he has a higher rent without any advantage of market; for it is probable that the advance of the value of his grain is more than counterbalanced by the diminution of the quantity. But it should not be forgotten that this diminution in the quantity of his grain is not all loss to the farmer. His original rent is founded upon the presumption that his land will grow a certain quantity per acre; but this quantity is the average of a number of years, so that if in one year he falls short of the quantity, it is reasonable to suppose that in other years he exceeds it. When we consider, too, that he is, or ought to be, making improvements, it is fair to presume that he exceeds the estimated quantity upon which his rent was originally based, much more frequently, and more largely, than he falls short of it. Whilst, however, I am of opinion that the agriculture of England and Wales generally is retarded by the practice of withholding leases, or rather of not insisting upon their acceptance, I wish it to be understood that I do not for a moment recommend an indiscriminate granting of leases to occupiers of farms. The owners of small farms, for instance, will feel that they can seldom enter safely into contracts for a long term of years with the class of tenants who compete for small farms. Their narrow means, their want of capital, renders their covenant of little, if any value. And again, if upon many large estates the owners were suddenly to require and to insist upon a change involving a spirited and enlightened system of farming, and were even at the same time to hold out to their tenantry the security of leases, on corn or other produce rents, it would be utterly impossible, in numerous cases, to carry out the commendable objects of such landlords, with the bulk of the tenantry existing upon such estates. An immense proportion of the soil of England and Wales is occupied by men of inadequate capital; another large proportion is held by men devoid of energy and enterprise, who are so wedded to their antiquated ways, that they will hardly look over their own hedges to see what is being done by their more spirited neighbours. There cannot be any doubt that if it were the practice of an estate to insist upon the acceptance of leases, landlords or their agents would be constrained to sift the resources and circumstances of applicants much more closely than they do at present, when letting farms merely from year to year. The consideration weighs with the landlord or agent that the contract is but for a year, and that if the tenant does not go on pretty well he can be removed by a six months' notice; but we all know that such is the generosity and forbearance of English landlords, generally, that when once an indifferent tenant becomes seated in a farm, he is generally allowed to remain there; he is tolerated and borne with long after a proper

regard either to the landlord's interests or the public interests has suggested the reasonableness and the propriety of his being removed. I have lately availed myself of an opportunity of witnessing the effect of leases for 21 years, granted in a somewhat indiscriminate manner about 14 years ago to a tenantry occupying an estate of some extent in Cheshire. The Beeston Castle and Peckforton estates, of about 4000 acres, at the period referred to, belonged to the late Sir Thomas Mostyn, as tenant for life, with remainder to a party whose pecuniary embarrassments gave grounds for apprehension that he would, if he came into possession, bear hard upon his tenantry. Sir Thomas—than whom a better landlord, or kinder hearted man never lived—offered, under the powers he possessed, leases for twenty-one years to such of his tenants on those Cheshire estates as might choose to apply for them, and his agent might deem fit to be intrusted with them. Thirteen of the principal tenants on those estates asked for, and obtained, leases—the only test of fitness applied to the applicants being their having paid up their rents. The leases have been granted about 14 years. I went over the estate in September last with my relative and namesake, who has been familiar with every corner of the property for 30 years, and who settled the terms of the leases 14 years ago, which were very well and equitably arranged. The farms in question being dairy farms, the rents were made to fluctuate with the price of cheese. From the testimony of my relative, and that of some intelligent parties who accompanied us, and from my own recollections of the property, I can state, that only two individuals out of the whole number of 13 have made the least use of the security and advantages afforded them by their leases. As to 11 out of the 13, they and their land have remained alike, as it were, in *statu quo*; the idea of improvement never for one moment appears to have entered into their minds. Some of those men—the greatest part of them—had not the necessary means of effecting material improvements: they were needy men; some few were in better circumstances, and better results might have been expected. There were, however, two individuals, whom I may hope without offence to name, who had the good sense to set to work at once to put their land into condition. The name of those tenants are Mr. Bird, of Beeston Hall, and Mr. Jones, of Park Gate, a farm near Beeston Castle, both near Tarporley. Their process of improvement consisted in draining and in dressing heavily with bones. They drained extensively, and they manured with bones at an expense altogether of from 10*l.* to 12*l.* per acre. Mr. Bird's leasehold consists of two farms, one of about 330 acres, the other of about 84 acres. I heard Mr. Bird affirm that such was the change produced by management upon the farm of 84 acres (where he, when he was first married, was by his late father placed to live) on nearly the whole of which he expended 10*l.* per acre at the commencement of his term, that where his predecessor made about 25 or 30 cwt. of cheese per annum, he (Mr. Bird) made upwards of four tons, and maintained besides as much stock in horses and young cattle, unproductive of milk, as had been before maintained. Other portions of Mr. Bird's land, besides the 84 acres farm, have been much improved, and he has been repaid, and is being repaid, in a degree that is satisfactory to him, and to which his good management and industry entitle him. The case of Mr. Jones is scarcely less striking. His farm is about 200 acres. He adopted a course of treatment similar to that of Mr. Bird. It is known to all his neighbours, and I heard him admit it, that before he drained and boned, he kept only 25 cows. His land now maintains 46, and such of his lands as were in tillage before are in tillage still, and partake of the good management bestowed upon his Grass lands. I consider the case of those Cheshire estates very interesting, in connection with the subject of leases, and I give the names and addresses of Mr. Bird and Mr. Jones, that those who take any interest in the matter may, if they please, take occasion to see them and their farms. This case proves how important, in a national as well as individual point of view, would be the effect of granting leases to well-selected tenants, and how absolutely necessary it would be, under a system of leasing, to constrain the drones and the incapables to move on or out of the way. If individuals who advocate leases imagine that material advantage would ensue from the granting of leases to tenants *indiscriminately*, those individuals labour under great mistake. There must be a great disturbance of the present occupiers—a great severing of old connections, and a great uprooting of old attachments, if the system of leasing is to be suddenly attempted with a view to national and to individual benefit. Landlords cannot, with common prudence, demise their estates for a long term of years, and accept the covenants of parties who have nothing to lose, and who, if they had leases tomorrow, would not be able to turn them to the least advantage. In reference to the length of leases, I think where much improvement is to be made, our English term of 21 years, or the Scotch term of 19 years, very fair. If a farm, when leased, be in good condition, there is less necessity for extraordinary outlay, and consequently less necessity for the security of a lease which extraordinary outlay requires. In many cases, however, where outlay is to be made by the tenant, a lease for 7 years certain, and afterwards from year to year, and until a two years' notice to quit be given, would afford perfect security to the tenant, and would be conceded by the generality of landlords with less hesitation than a term of 19 or 21 years. I think, whatever the term may be, in the event of the death of the lessee, the lessor should, in addition to his ordinary powers of re-entry, for breach of covenant, have power to determine the tenancy before the expiration of the term by a two years' notice to quit. This period would afford time and opportunity to test the qualifications of the party introduced into the tenancy. If his management were good, public opinion, if the right feeling of an English gentleman were wanting in the landlord, would generally secure the tenant against unfair disturbance or molestation. I think such a power to determine farming leases as the one I have suggested ought to be reserved to lessors, and I think it is one with which English landlords may safely be entrusted. At all events, such a reservation of power to the landlord might be made perfectly unobjectionable, by a stipulation that, in the event of its being exercised, the tenant should be paid for all permanent improvements made with the acquiescence of the landlord or agent, of which he had not had time to reap the full benefit. As far as my experience of estate management and of farming leases goes, I should say that there is hardly any system of letting worse than that of leasing upon lives. I have had an intimate acquaintance with some extensive estates (particularly in South Wales) which had been demised for three lives at low rents, a consideration in money having been paid for the leases when granted. I first knew them at the period when the leases were beginning to drop in. The farming was in almost every case the very worst in the country, and although the rents were only one-fourth or one-third of the rack-rent value, most of the tenants had been reduced to beggary by their indolence and bad management. It seemed as if towards the expiration of their leases, when their leases hung upon one or two old lives, for instance—it seemed as if the uncertainty of their tenures had paralysed all their exertions. They would not improve, considering the time was near at hand when the lease must expire, and an advance in rent ensue. Another topic to which I will briefly advert, is that of the rate of interest to be charged on money invested by landlords in improvements on farms already let at fair and equitable rents. How often do we see gentlemen, in their desire for extended landed possessions, who, whilst they already have lands almost totally unimproved, imperfectly drained, imperfectly fenced, with bad roads and worse buildings—lands on which capital may be made sufficiently remunerative—how often do we see them borrowing money at four or five per cent. to pay for estates bought to pay two or three per cent. I submit, it is very obvious that, instead of indulging the passion referred to, it would be better for the interests of agriculture, and certainly, in a pecuniary point of view, much better for such purchasers and their families, were they to expend capital on such of their lands as allowed of permanent improvement, although that improvement might not be calculated to admit of the tenant bearing an increase of rent to a greater extent than five per cent. on the outlay. The tenant farmer, however, must obviously lay his account for a better rate of interest; for, in addition to the interest of his money expended in permanent improvements, he has his capital to redeem. If holding under a lease, it will depend upon the term remaining in such lease; if holding under a tenancy from year to year, it will depend upon the confidence he may have in the honour and fairness of his landlord how he ought to lay his calculations for redemption of outlay. In connection with our present subject it may be remarked, that where a tenant is highly rented, and somewhat crippled in his circumstances by the drain thereby occasioned, a landlord, instead of reducing the rent, may often, by a little judicious expenditure in promoting, or altogether executing, an improvement, sustain the rent, and confer a greater boon on the tenant than a reduction of rent would have conferred. It is always matter for the exercise of judgment and discretion, whether the landlord should charge any per centage at all upon an outlay made under such circumstances. I shall now bring my observations to a close, merely observing that it is impossible to travel through England and Wales, in any direction, without feeling a strong conviction that there must be some serious obstacles to the investment of capital in agriculture. The people at large are deeply affected by every measure which has a tendency to fetter the productive powers of the soil, and to depress one of the largest and most valuable classes in the country. It is clearly their interest that corn and other provisions shall be supplied in abundance; and, perhaps, the people of England and Wales may justly complain of the want of leases as one of the principal causes which check the improvement of their own territory."—On the conclusion of the Essay, it was proposed by Lord Lyttelton, and seconded by J. H. H. Foley, Esq., "That the thanks of this meeting be given to Mr. Maughan for his very valuable Essay." The motion was, by acclamation, carried. Both Lord Lyttelton and Mr. Foley, in speeches of considerable length, expressed their concurrence in the views on leasing embodied in Mr. Maughan's Lecture, and avowed their readiness to act upon them. After an animated conversation on the subject, the following resolution was carried: "That it is the opinion of this meeting that the present system of letting farms—large farms especially—to tenants to hold from year to year, begets, on the one hand, incaution in the landlords in the selection of tenants as regards their pecuniary resources and personal fitness; and on the other hand, affords mischievous facilities to men without calculation and competency for obtaining farms exceeding their skill and capital to manage, and begets in tenants generally holding from year to year an indisposition to hazard any outlay not required by ordinary and routine management; and that it is further the opinion of this meeting that the granting of farming leases for a term of 21 years, or thereabouts, on corn or other produce rents, to tenants carefully and judiciously selected, would tend, in an eminent degree, to elevate the pursuit of agriculture, and would incite to the general adoption of the best systems of husbandry."

Reviews.

The Industrial Resources of Ireland. By Robert Kane, M.D., &c. &c. Hodges and Smith, College Green, Dublin.

"In other countries it has been the most anxious care of Government, and of those entrusted with the superintendence of education, to ascertain the nature and amount of their means of promoting industry, and extending the employment of the people. It is thus that every year sees the continental nations making such giant strides in manufacturing activity. It is thus that the physical disadvantages, which had so long kept them back, are gradually being lessened in importance. If similar zeal and intelligence were manifested in developing the resources of this country, there would be no fear of the result. As circumstances, however, do not admit of this being done, the publication of even the short and imperfect sketch, which alone could be drawn up by an unaided individual, may be useful in awakening the attention of those practically engaged upon those subjects, and may lead to more extensive observation, and more detailed inquiry."

This extract from the Preface of this work is an exceedingly modest announcement of the Author's motive in its publication. This "short and imperfect sketch," as he terms it, of Ireland's resources will, we doubt not, be eminently useful in teaching her people how to exert and direct their industry profitably; and it will be the means not only of thus *creating* capital, but of indicating the many opportunities which exist in that country for its profitable *investment*.

Among the subjects of discussion in this volume are the following:—the circumstances of Ireland with regard to fuel—the water-power of Ireland—its manufacture of iron—the geological character of the country—its mines of copper, lead, &c.—its agricultural industry—its means of internal communication—the cost of labour in Ireland—its supposed want of capital—its want of industrial knowledge. It is only to the chapters referring to the Agriculture of this country that we shall direct the attention of our readers; and we can truly say that they will find in them much on the general bearings of the subject—many instances of what is now acknowledged to be the chief source of future improvements in practice, the skilful application of scientific truth—much information on the cultivation of particular plants—in short, much that will greatly interest those who may be neither personally nor specially interested in the great object of the Work.

It is our wish to convey an accurate idea of this portion of the volume—extending over about a hundred octavo pages of small print—and, in order to this, we cannot do better than transcribe the headings of the two chapters into which it is divided, and occasionally quote an illustrative passage from the pages to which they refer.

The following, then, are the subjects which have engaged the Author's attention:—"*The agricultural industry of Ireland—its importance as an occupation—relations of agriculture to manufactures—natural fertility of the soil of Ireland.*" On this last we quote the opinion of Arthur Young, who says of Limerick and Tipperary—"It is the richest soil I ever saw, and such as is applicable to every wish. It will fatten the largest bullock, and at the same time do equally well for sheep, for tillage, for Turnips, for Wheat, for Beans, and, in a word, for every crop and circumstance of profitable husbandry. You must examine into the soil before you can believe that a country, which has so beggarly an appearance, can be so rich and fertile."

We continue our Table of Contents. "*Distribution of the surface of the country—office of plants—correlative functions of the mineral, vegetable, and animal kingdoms—composition of plants—origin of the soil—connexion between the fertility of the soil and its composition—examples of fertile districts—nature of the soils of various parts of Ireland—composition of subsoils—organic elements of the soil—mechanical and physical office of the soil—of drainage; its importance to Irish agriculture—action of plants on the soil—of exhaustion—composition of the most important crops—of manures—composition and properties of the most important native manures—of lime and limestone; marl; sea sand; coral sand, its nature.*" Again we transcribe an interesting passage, descriptive of the extent and employment of these sources of manure, to which we have parallels in England in the extensive use made by farmers in Cornwall of the sea-sands accumulated on its northern coasts:—

"The shell banks of Lough Foyle form, when the tide is out, extensive flats, which are firm enough to be walked on without any inconvenience, and they are resorted to by numerous boats for loads of shells; and though this system has been pursued for more than a century, they exhibit no appearance of a failure in the supply. The shells hitherto examined are all of recent species; and it becomes a question whence they came. There are engaged in raising the shells

225 men for 26 weeks, at 10s.		£3285
50 boys	at 6s.	290
The cost of the labour alone is thus		£3575

There are annually employed about 94 boats, of tonnage from below 8 to 60 tons. The aggregate tonnage of 41 of the largest boats is 1306 tons. The total quan-

city of shells raised each summer is about 59,496 tons, which on the shore immediately opposite the bank sell for 1s. per ton; but at Derry and Strabane for 1s. 6d. to 2s. per ton. Altogether Captain Portlock considers the shell banks of Lough Foyle to be worth 5000*l.* per annum to the country. 'They are particularly useful in bringing bad lands into cultivation, and in ameliorating stiff wet clays, deficient in calcareous matter, being applied at the rate of from 30 to 60 barrels per acre. They are preferred to lime, as warming and brittleing the land."

"*Value of those sands dredged upon the north and south coasts—of gypsum; of sea-weed; of bones; farm-yard manure; its composition and relative power—importance of its preservation and suitable economy to practical agriculture. Of rotations—relation of Corn crops and green crops—amount of food produced by various systems of culture—influence of different cultures in the exhaustion or amelioration of the soil—size of farms in Ireland—principle of consolidation not as applicable to Agriculture as to manufactures—relation of the size of farms to the population—relative profit and employment afforded by large and small farms—average available farms for existing population.*" On these latter subjects we venture to quote a short passage from a lengthened argument, which requires, however, to be perused throughout thoroughly to appreciate it:—

"In his valuable work on Agriculture, Professor Low gives some estimates, from which it results that he considers a 500 acre farm to give an amount of occupation equivalent to the employment of 20 persons throughout the entire year. Now it has been already shown that the area of land available for cultivation is about 18,000,000 of acres, made up of:

Land actually cultivated	13,464,300 acres.
Land capable of cultivation . . .	4,500,000 ,,

Now if this be divided into 36,000 farms, of 500 acres, there will be given by their cultivation employment for 720,000 individuals; but as the actual agricultural population amounts to 5,406,743, the difference, or four millions and a half of human beings, will be thrown on the world without any means of subsistence."—"On the other hand, as the total number of existing agricultural families is 974,188, it results that from the available land there could be allocated to each a farm of 17 statute acres. That this quantity is sufficient to support a family, paying full rent, is a matter of which there is no doubt."

"*Secondary uses of food crops—manufacture of Potato-starch, sugar, and spirits—composition of different kinds of Potatoes—manufacture of Beet-root sugar; its economic circumstances—of fibre crops—cultivation of Flax and Hemp—composition of ligneous fibre—mode of culture and preparation of Flax—principles which it gives off in steeping—average crop of Flax—its value—uses of the Flax residue as food and as manure—Flax manufacture and linen trade—total value of Flax grown in Ireland—exertions of the Royal Dublin Society and Flax Improvement Society, and their results—employment given by the Flax and linen trade—tables of mill power and of exportation of Flax and linen—localization of this industry—favourable situations for it—culture and composition of Hemp—conclusion.*"

Our last extracts shall be on the cultivation of Flax—a crop which is becoming every year more extensively cultivated in this and the sister country:—"Mr. Crosthwaite, whose intimate acquaintance with all branches of this industry renders his authority highly valuable, considers that there are about 100,000 acres under Flax in Ireland, and that the produce is about 30,000 tons, of an average value of 50*l.* per ton. This is 6*s.* 3*d.* per stone, and should give about 12*l.* 10*s.* for the usual produce of the statute acre."—"The Flax, when it has grown to suitable maturity, according as the design is to allow it to ripen its seed or not, is pulled, and either immediately, or in the next spare season, according to the circumstances of the locality, it is subjected to the process termed rotting or watering. In the stem of the Flax there may be recognised three structures—the outer skin or epidermis, covering a close network of fibres which incloses the plant as in a sheath, and in the centre a stem of dense pithy material. The fibrous network is connected together by a glutinous matter which must be decomposed before the fibres can be separated from the stem, and it is to soften and rot this substance that the plant is steeped. If the steeping be continued too long, the fibre itself may rot, and be weakened and injured in quality; if the steeping be not continued long enough, the fibres are not thoroughly separated from each other, and the quality of the Flax is coarser than it might be."—"When the Flax is steeped, the water acquires a darker colour, a disagreeable odour, and, it is well known, becomes poisonous to fish. This arises from the solution of the glutinous material which had cemented together the pure fibres."—"The author of the Survey of Somersetshire (Mr. Billingsby) says: 'Having myself cultivated Flax on a large scale, and observing the almost instantaneous effect produced by the water in which the Flax was immersed, I was induced, some years ago, to apply it to some pasture land, by means of watering-carts similar to those used near London for watering the roads. The effect was astonishing, and advanced the land in value 10*s.* per acre.'"

This part of the subject is illustrated by analyses, executed by the author, of the Flax-plant, its ashes, the extract in the Flax-steep, &c. Professor Kane's work is one of national importance.

The British Farmer's Almanack and Diary of Agriculture and Gardening for 1848. Company of Stationers. London.

This is another well-compiled Farmer's Almanack. Its Agricultural Calendar has been written by a gentleman who, we happen to know, is thoroughly well qualified for the task.

Miscellaneous.

Practice of Irrigation.—The first operation on the intended meadow is, to free it thoroughly of water by draining. If springs exist, they should be cut off by drains of sufficient depth to reach the source of injury. But, in addition to this, the land, if the soil is clayey, or rests upon a tenacious subsoil, should be effectually furrow-drained, so as to afford a ready egress to the water underground. The land is then to be levelled and otherwise prepared. If it is already in old turf, it will be well to pare off the sward with the spade, and after having dug and prepared the ground, to replace the turf. In this manner the meadow will be ready for the reception of the water, as soon as it is formed. But should there be no turf upon the ground, or should this turf be filled with useless or innutritious plants, the land should be thoroughly worked, levelled, and otherwise prepared, and then sown with the suitable Grass-seeds. These Grass-seeds may be sown in autumn. We cannot, however, in this case, admit the water during the first winter. We must retain the land in pasture for the whole of the following winter and summer, so that the young plants may establish themselves in the soil. But in the second winter we may generally admit the water. The ground may be in part prepared by the plough, and we may even economise expenditure by taking a crop of some kind before we begin to level and otherwise form the meadow; but generally it is better to proceed at once with the formation of the meadow, and employ the spade in place of the plough for levelling and preparing the ground for the reception of the Grass-seeds in autumn. Along the higher side of the meadow is first to be formed the main conductor, to which the water is carried, and from which it is conveyed over the surface of the meadow. The earth taken out of this trench is to be employed in banking it, and filling up hollows in the surface of the ground. The size of the main conductor must be proportioned to that of the meadow, and the quantity of water to be conveyed. The next operation is, forming the main drain, at the lower part of the land to be flooded. It is of the same size as the main conductor, and the earth taken out of it is to be employed in banking or filling up hollows. The surface of the meadow, supposing it to be flat, is now to be formed into beds or panes, from 30 to 40 feet in width, extending from the main conductor to the main drain. These beds may be elevated about 12 inches at the centre; they are not curved like the ridges of a ploughed field, but form inclined planes from the centre to each side. At leaving the main conductor they may be 20 inches wide, gradually narrowing to nearly a point at their termination when they reach the surface. If stops of solid earth are left, these may be six inches either way, with their diagonal in the line of the feeder, and such of them as are not required may be afterwards removed. The earth taken out of these feeders is to be employed in making good their own banks, and in levelling inequalities of the surface. Corresponding with the feeders, and alternating with them, are to be formed the series of subordinate drains, communicating with the main drain. They are of the same dimensions as the feeders, with this distinction, that they are widest and deepest where they communicate with the main drain, and become gradually smaller to the upper part of the meadow, where they terminate. The surface of the meadow being formed, the Grass-seeds, where no turf has been reserved, are to be sown. The following admixture of Grasses will be found suitable:—1. Alopecurus pratensis—meadow fox-tail; 2. Phleum pratense—meadow cat's-tail; 3. Agrostis alba—marsh bent-grass; 4. Poa trivialis—rough-stalked meadow-grass; 5. Poa pratensis — smooth-stalked meadow-grass; 6. Festuca loliacea—spiked fescue-grass; 7. Festuca pratensis—meadow fescue. When the old turf has been replaced, the water, it has been said, may be admitted in the first winter; when Grass-seeds have been sown, the water cannot be admitted until the second winter, and sometimes even not until the third. The ground should be depastured with sheep during the first summer, to such a degree as to prevent the plants from putting forth their flowering stems and producing seeds. The next point to be considered is the management of the meadow when completed. At the beginning of October, we are to prepare for admitting the water. To this end the drains and feeders are to be cleaned out, and the banks where injured repaired. The main sluice is then to be withdrawn, when the conductors and feeders will be gradually filled. The next point is to adjust the water in the several feeders. To this end the workman is to observe that each feeder, beginning with the first in order, receives a due quantity of water. If not, he enlarges the mouth so as to allow the proper quantity to enter. He then adjusts the stops in the several feeders, so that the whole surface of the beds shall be covered equally about an inch deep with water. During this and the three following months—namely, November, December, and January, the ground is to be regularly flooded for 15 or 20 days at a time, with intermissions at each time of seven or eight days, during which the ground is to be laid perfectly dry. Further, when severe frost is threatened, the water is in like manner to be withdrawn, so as that it may not freeze upon the surface. During this, the principal periods of flooding, the meadow is to be inspected every three or four days, to see that no interruption from the breaking of banks, accumulation of weeds, or otherwise, is given to the flowing of the water. When the spring months arrive, and the Grasses begin to grow, the periods of flooding are to be shortened. In the month of February the water should never be allowed to flow above six or seven days at a time, and in severe frosts it should be withdrawn, so that no ice may be formed upon the meadow. The same management, shortening to five or six days the periods of flooding, may be continued till the middle of March, by which time the meadow will be ready for receiving any kind of stock. In this manner, an early supply of herbage is obtained, and after the stock has been removed, as by the beginning of May, the flooding may be resumed and continued till near the end of the month, so as to prepare the meadow for hay. But often this spring feeding is not resorted to. The irrigation is continued during the months of March, April, and until the middle of May, when it finally ceases. But during this period, the frequency and length of time of watering are gradually diminished from five or six days in March, to two or three in the latter period of flooding. Caution is required in flooding as the season advances; because, were the finer Grasses to be too long submerged at this period of their growth, they would be injured and destroyed. The actual periods of flooding differ with the state of the season and the nature of the soil. A practical rule adopted by irrigators is, never to continue to flood when a white scum is seen to form on the surface of the water, for this indicates that the putrefactive fermentation has commenced in the turf. By the middle of May, or rarely later, the flooding is to cease, and the land to be laid thoroughly dry. The Grasses will now grow with great luxuriance, and produce an abundant crop of hay. When the hay is removed, the aftermath is depastured, after which the same process of flooding recommences. Sometimes, after the hay is removed, the ground is again flooded; but, in this case, no sheep must be admitted on the flooded land, or, if admitted, they must be such sheep as are to be immediately killed; for this summer-flooding never fails to bring with it the disease of rot in its most destructive form. In place of the meadow being applied to the production of hay, it may be applied to the production of green forage for soiling. This is a more profitable mode of applying the watered meadow than for the production of a crop of hay. Three crops in this case may be taken, the meadow being flooded after each crop is removed.—*Professor Low, on Landed Property.*

Notices to Correspondents.

The letter, *J. C., Kent*, has been received: too late for publication this week.

Acorns as food for Pigs.—*T. D.*—See page 699.

A Leaking Tank.—*Bingo.*—The recommendation to put Oatmeal into such a tank was not ours; we cannot speak of the efficiency of such a plan, and should think it unsuited to your case.

Bacon.—To Readers.—*A.*—How can I prevent the formation of *rustiness* in bacon? Does it arise from improper curing, or improper *keeping?*

Books.—*Broadway.*—The works you want are published by the Society for the Diffusion of Useful Knowledge.

Bouggy Land.—*Atrickaey.*—Lime it at the rate of 100 bushels per acre; in spring you can apply ordinary farm manure.

Carrots.—*Subscriber.*—They can be given to milch cows, with advantage both to the health of the animal and the quantity and quality of the milk. We have given 100 lbs. weight a day to cows, along with the Wurzel.

Farm Accounts.—*J. M. M.*—There are some instructive chapters on this subject in Stephens's "Book of the Farm." The best principle of any system of accounts is of course that of double entry.

Gas Lime.—*Sheiravel.*—Your compost will be a powerful fertiliser. Turn the lime 3 or 4 times, at intervals of 8 or 10 days, before soaking it and the tan with urine. A waggon-load ought to dress an acre.

Guano.—*E. F. A.*—Apply guano and all other manures whose value depends in any measure on soluble ingredients, early in spring—say first week in April—in wet weather.

Price of Turnips, &c.—*Anon.*—Swedes, 1*l.* per ton; Mangold Wurzel, 15*s.* per ton; Carrots, 2*l.* per ton. These are prices which we have known given for large quantities; but of course they vary somewhat.

Sheep.—*J. E.*—We understand the sheep at Whitfield Farm do not receive any chaff as food. They are all fed in the yard under shelter, on Swedes and oil-cake.

Spring Wheat.—*J. M. F.*—It may be sown if the land be drained, on any suitable day through the winter. It is generally sown in February. The Belle Vue Talavera is a good variety.

*** As usual, many communications have been received too late.

Markets.

SMITHFIELD, Monday, Dec. 9.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	4s	0	to	4s	4	Best Downs & Half-breds	4s 0 to 4s 6
Best Short Horns	3	10		4	0	Best Long-wools	3 10 4 2
Second quality Beasts	3	6		3	8	Ewes and second quality	3 0 3 6
Calves	3	8		4	6	Pigs	3 4 4 4

Beasts, 4180; Sheep, 30,140; Calves, 90; Pigs, 418.

Our supply of Beasts to-day is very large, with a fair proportion of good quality. The importation of Irish Stock is becoming an important feature in the consignments to our Market; we have to-day about 600 direct from Ireland. Everything, in consequence of the supply, has received a check; yet, the weather being good, the best qualities find purchasers at about the same money; in some instances a few of the best Scots make nearly 4s 4d, and some choice Short Horns 4s 2d. Trade is very heavy [illegible] the middling sorts, and several remain unsold. Sheep [illegible] are rather more plentiful; the best qualities, however, are [illegible] very abundant, and fully support our late quotations. [illegible] as usual so near Christmas, inferior kinds are difficult to [illegible] of. Veal-trade is heavy, but the best qualities are making about the same price as of late. Pork-trade is heavy.

Friday, Dec. 13.

The supply of fresh Beasts up to-day is but moderate, the time of year considered. We have a few lots of very superior quality, but the trade is heavy amongst them. It still being some time to Christmas, the butchers are not very eager to buy. The prices are about the same as on Monday. There are a great many second-rate Beasts, and several left unsold. Veal-trade is considerably worse; it must be a very choice Calf to make 4s 4d. We have rather a large supply of Sheep for the time of year, and trade is very heavy; a great proportion are of middling quality, which are very unsaleable. The best Sheep are worth a trifle less than on Monday. Pork is lower, prices ranging from 3s 4d to 4s.

Beasts, 1396; Sheep, 4480; Calves, 147; Pigs, 270.

d, West Smithfield.

HOPS, Friday, Dec. 13.

We have again more demand for Hops at improved prices.

Farnham & Borough, Hop-Factors.

COVENT GARDEN, Dec. 14.—The supplies of most articles have been tolerably good, and, in consequence of the frosty weather, prices have been considerably on the rise. Trade is somewhat brisker. Among Fruit, Pine-apples continue to be sufficient for the demand; they consist chiefly of Queens and Black Jamaicas. A few Hothouse Grapes have been offered during the week, and foreign sorts are pretty plentiful. The supply of good Dessert Apples is equal to the demand, and Pears of good quality are also abundant. Chesnuts, as well as other nuts, are scarcer, and consequently dearer than they were last week. Oranges are consequently much dearer. Good samples of Seakale and Asparagus are offered; for the latter, however, there is little demand. Likewise slightly on the rise. Among vegetables, White and Purple Broccoli is good. Cauliflowers are good; but they are scarce, and Turnips and Carrots are considerably advanced in price. Leeks are likewise dearer, as are also Parsley and Celery; some specimens of the latter are very fine. A considerable quantity of Dutch Potatoes are in the market; they are said to be good in quality, and are selling at 3d. per lb. French Beans have been offered during the week at from 3s. to 4s. per 100. A few Tomatoes are still to be had; but they are becoming very scarce. Lettuce, Endive, and other salading, are tolerably plentiful, and pretty good for the season of the year. Among Cut Flowers we noticed Cypripedium insigne, Bignonia venusta, Luculia gratissima, Poinsettia pulcherrima, Gnidia pinifolia, Pentas carnea, Camellias, Epacrises, Heaths, Heliotropes, Cinerarias, Amaryllises, Azaleas, Narcissus, Chrysanthemums, Tulips, and Roses.

FRUITS.

Pine Apple, per lb., 2s to 7s	Oranges, per dozen, 1s to 2s
Grapes, Hothouse, p. lb., 2s to 4s	— per 100, 5s to 12s

Salsafy, per bunch, 1s to 1s 3d	Chilis, per 100, 1s to 2s

POTATOES.—SOUTHWARK WATERSIDE, Dec. 9.

The supply during the past week has been unusually limited, in consequence of the prevailing east winds. The best samples went off readily, and towards the close the weather set in very severe, with some appearance of its continuance, which increased the demand for the best samples.

MARK-LANE, MONDAY, Dec. 9.

The supply of Wheat from Essex this morning was moderate, that from Kent and Suffolk good, and the whole met a tolerable sale on fully as good terms as this day se'nnight; in Foreign the business transacted was to a very limited extent only. There was less Barley offering than of late; fine malting qualities were taken on rather better terms; grinding and distilling found more inquiry at our quotations. Beans and Grey Peas must be written 1s. lower; White are unaltered in value. The quantity of Oats on sale continues moderate, but although prices are fully supported, the demand is not active.

FRIDAY, Dec. 13.

THE arrivals of Corn during the week have been very moderate, and the frost having closed the majority of the canals, and threatened to stop the navigation of the River, business generally has been very limited; we observe no alteration in the value of Wheat, but prices both for English and Foreign are fully maintained. Great difficulty is experienced in the disposal of the Barley left unsold from last day, but its value cannot be written lower. Beans and Grey Peas are unaltered, White continue inquired after. The quantity of Oats on sale is small, and meet a slightly improved demand about late quotations.

RURAL CHEMISTRY.

By EDWARD SOLLY, Esq., F.R.S.,

Experimental Chemist to the Horticultural Society of London, Hon. Mem. of the Royal Agricultural Society, and Lecturer on Chemistry, at the Royal Institution.

&c. &c. &c.

Extracts from the Introduction:—

"A knowledge of the chemical composition of soils and the various substances employed as manures enables us to comprehend the mode in which the latter act; and a knowledge of the nature of those substances which plants require, points out the best and most economical methods of restoring to the soil, by manures, those substances which plants remove from it."

"If the farmer knows what it is that gives the fertilizing powers to manure, and is aware of the nature of those substances, he will soon learn the best method of preserving and using them: he will then understand how to make the most of the various sources of manure at his disposal, and he will be enabled readily to save much, that, for the want of such knowledge, would otherwise be lost."

THE ATHENÆUM

JOURNAL OF LITERATURE, SCIENCE, AND ART,

(Stamped to go free by post, 5d.) contains:—

Reviews, with copious extracts, of every important New English Book, and of the more important Foreign Works.

Reports of the Proceedings of the Learned and Scientific Societies, with Abstracts of all Papers of Interest.

Authentic Accounts of all Scientific Voyages and Expeditions.

Criticisms on Art, with Critical Notices of Exhibitions, Picture Collections, New Prints, &c.

Music and Drama, including Reports on the Opera, Concerts, Theatres, New Music, &c.

Biographical Notices of Men distinguished in Literature, Science and Art.

Original Papers and Poems.

Miscellanea, including all that is likely to interest the informed and intelligent.

The Athenæum is so conducted that the reader, however far distant, is, in respect to Literature, Science, and the Arts, on an equality in point of information, with the best-informed circles of the Metropolis.

Card racks, ... per pair. Note and cake baskets, 35s. to 20s. each. ... tables, 10l. 10s. to 2l. 10s. Leather ... complete, dressing apparatus, 15l. 10s. to 3l. 10s. Pearl-and-ivory card cases, 3l. 10s. to 10s. each. Ivory hair brushes, 4l. ... per pair. Splendid cases of scissors, 10l. ... 6s. each. Ivory handled and other highly finished ... to 3s. each. Wharncliffe penknives, sporting knives, nail ... scissors, 3l. to 4s. each. Splendid cases of agate, pearl, and ivory dessert-knives and table knives, from 42l. to 6l. 4s. the case. A rich variety of plate, bronze, gilt, and papier maché and table inkstands, from 8l. to 7s. 6d. each. The quality generally of Mechi's manufactures, the elegance of their display, and the rare combination of excellence and economy, with a very extensive choice of stock, will amply repay the trouble of visiting his depôt, 4, Leadenhall-street.

HEAL AND SON'S LIST OF BEDDING—Containing a full description of weights, sizes, and prices, by which purchasers are enabled to judge what articles that are best suited to make a good set of Bedding, sent by post, on application to their establishment, the largest in London exclusively for the manufacture and sale of Bedding (no Bedsteads or other furniture being kept). HEAL AND SON, Feather Dressers and Bedding Manufacturers, 196, opposite the Chapel, Tottenham Court Road.

SEASONABLE FESTIVITIES.—The gaiety that reigns supreme at this festive season, when friends and lovers assemble at the social board, or whirl in the giddy mazes of the dance, induces both sexes to be more than usually desirous of shining in personal attraction, and to devote a greater share of attention to the toilet. It is at this particular season, that the VIRTUES and SINGULARLY HAPPY PROPERTIES OF THOSE AUXILIARIES OF PERSONAL BEAUTY, ROWLAND'S KALYDOR, ROWLAND'S MACASSAR OIL, & ROWLAND'S ODONTO, shine pre-eminent in their power; while the *white* and *swan-like neck*, the *rich luxuriant tress*, and the *Pearly set of Teeth* form admirable trophies of their INESTIMABLE QUALITIES! The august Patronage conceded by our Gracious Queen, and the several Sovereigns of Europe, together with the Beauties which adorn the circles of Princely and Regal Magnificence, and the confirmation by experience of the infallible efficacy *of these creative renovating Specifics*, have characterized them with perfection, and given them a celebrity unparalleled. As presents for both sexes, none can be more recommendatory, or more now in general use.

IMAGINATION AND FANCY; ... ENGLISH POETS, illustrative of those First Requisites of their Art, with Markings of the best Passages, Critical Notices of the Writers, and an Essay in answer to the Question, "What is Poetry?" By LEIGH HUNT. "This volume is handsomely printed, and beautifully bound in a new style of exquisite delicacy and richness. To institute a comparison with the contents of the Annuals would be absurd, at any degree of distance,—there is no more relation between them than between a street lamp and a fixed star: but in external beauty 'Imagination and Fancy' equals any gift-books that have appeared, and it will form a more enduring memorial than any other volume that might be selected as a gift for the coming season."—*Spectator*.

II.

Just published, Sixth Edition, in 3 vols. fcap. 8vo, beautifully illustrated, price 7s. 6d. each, in a handsome and uniform cloth binding, or 10s. 6d. morocco,

CHARLES GIBBONS „	59.	1st do.
CHARLES GRAY „	69.	1st do.
JAMES STEDMAN „	75.	1st do.
ANN SUTTLE „	67.	1st do.
RICHARD STOYLES „	77.	1st do.

No person will be allowed to vote whose Subscription for 1844 is unpaid on the day of Election.

EDWARD R. CUTLER, Secretary, 97, Farringdon-street.

JESSOP'S NURSERY, Cheltenham, Established in 1815, from its extensive connection offers peculiar advantages to Noblemen and Gentlemen requiring Gardeners, Foresters, or Farm Bailiffs, of established skill and reputation. All communications promptly attended to.

TO THE CULTIVATORS OF ROSES.

R. B. BIRCHAM, Hedenham Rosery, Bungay, Suffolk, begs to offer the following Select ROSES, which he can with confidence recommend, as possessing superior quality. A purchaser selecting 12 different kinds from this list, R. B. B. will be happy to supply at 20s. The plants are strong and healthy, and varying in height of stem from 1½ feet to 3 feet.

Agnes Sorel	Aurelie Lamare	Las Casas
Dénna Sol	Brissis	Idalize
Duchess of Kent	Buffon	Jambart
Duchesse d'Orleans	Crivelle	Julie
Emerance	Duc de Trevise	La Splendeur
Illustre Beauté	Egle	Nelly
La Ville de Londres	Fleur d'Amour	Neequet
Mrs. Rivers	Gil Blas	Blairii, No. 2
Nicolate	Gurin's Gift	Charles Louis
Petite Beauté	Guin's Desdanes	De Candolle
Semilasso	Leo the Tenth	Fulgens
Theodora	Lionel Dumouriier	George the Fourth
La Ville de Bruxelles	Madame Debarry	Eclatante (Moss)
Voluminense	Reine de Perpetue	Princess Royal
Aglae Dusart	Triomphe de Laguette	Prolifere
Agnodier		Pompone
Antonine d'Ormoise		

Also strong plants of Climbing Roses (Evergreens), at 6s. per dozen. These Roses will make shoots upwards of 6 feet long in one season, and are very suitable to cover unsightly fences, walls, stems of trees, &c.

Descriptive Catalogues forwarded upon prepaid application. Plants gratis, to compensate for distant carriage.

Hedenham, Dec. 21.

THE ARBORETUMS, QUEEN'S-ELMS, BROMPTON, NEAR LONDON, AND EAST COWES PARK, ISLE OF WIGHT.

RAMSAY BROTHERS, LANDSCAPE GARDENERS, Contractors for Planting, Earthwork, Road-making, Forming Ornamental Waters, and Improvers in general of Landed Property.

Plans and Estimates submitted, and works contracted for in any part of the kingdom.

Messrs. R. invite Noblemen and Gentlemen to an inspection of their choice stock of Ornamental Plants, which have been selected for the Lawn, the Parterre, and the Shrubbery, and now growing at Queen's-Elms, one mile from Hyde Park Corner.

ROSES, HARDY HERBACEOUS PLANTS, AND HOLLYHOCKS.

WM. JACKSON and Co. beg to offer Collections of the above from their select Stock on the following very reasonable terms:—

100 Dwarf Roses in 50 named sorts, for 20s.
100 do. do. 100 do., fine sorts, 35s.
100 do. do. 100 do., very fine sorts, 50s.
20 Beautiful Scotch Roses, with names, 10s.
25 Standard Roses, including the fine Moss and Hybrid Perpetuals, 40s.
10 Do. do. do. do., 75s.
100 Showy Herbaceous Plants, in 50 named sorts, for 25s.
100 Do. Do. 100 do., 35s. and 40s.
50 Very fine showy do. do., in 50 do., 20s.; including several new and beautiful species and varieties.
100 Fine proved Hollyhocks for 35s.

The above are well grown; the Dwarf Roses on their own roots, and from the same stock as those which gave such general satisfaction last season. Plants given to compensate for long carriage. Catalogues will be forwarded on receipt of two postage stamps.

A remittance or reference respectfully solicited from unknown correspondents.—Cross Lanes Nursery, Bedale, Yorks., Dec. 21.

UNDER THE PATRONAGE OF HER MAJESTY.

J. G. WAITE, WHOLESALE SEEDSMAN, 1 & 4, Eyre-street Hill, Hatton Garden, London, returns his best thanks for the very liberal support he has hitherto received, and begs to call the attention of his friends and the public in general to the following reduced scale of prices of a small portion of his very extensive stock:

	£	s.	d.
Waite's Queen of Dwarf Peas . . . per quart.	0	7	6
A splendid new variety, growing only 1 foot high, producing a larger pod than any of the same habit; the seed is quite distinct from all others, and larger than any Dwarf Pea in cultivation. It has been grown at the Royal Gardens at Frogmore, and approved of as a new variety, and also at Her Majesty's table, for its superior flavour.			
Beet, Waite's Blood-red . . . . . per cwt.	8	8	0

„ Large ditto . . . . . „	5	12	0
„ East Ham . . . . . „	6	0	0
„ Sugarloaf . . . . . „	7	0	0
„ Imported Red Dutch . . . . . „	10	0	0
Cale, fine green curled . . . . . „	5	0	0
„ large Scotch . . . . . „	4	0	0
Celery, Red Giant . . . . . „	5	12	0
„ White ditto . . . . . „	5	12	0
„ Soup . . . . . „	4	0	0
Lettuce, White Cos . . . . . „	28	0	0
„ Drumhead Cabbage . . . . . „	28	0	0
„ Bath Cos ditto . . . . . „	23	0	0
„ Hammersmith Hardy Green . . . „	9	16	0
Salsafy . . . . . „	16	0	0
Scorzonera . . . . . „	14	0	0
Cucumber, Cuthill's Black Spine, warranted true, per oz.	0	12	0
„ Man of Kent . . . per 100 seeds	0	5	0
„ Victory of Suffolk . . . „	0	5	0
„ Weedon's Black Spine . . . „	0	5	0
Melon Cabul (true) . . . . . „	0	8	0
„ Beechwood (true) . . . . . „	0	7	6
Mignonette . . . . . per cwt.	7	0	0
Candytuft, purple . . . . . „	8	8	0
„ scarlet . . . . . „	11	4	0
„ new white . . . . . „	11	4	0
Convolvulus, Major (fine mixed) . . . „	14	0	0
„ Minor . . . . . „	10	0	0
Virginian Stock, red . . . . . „	8	8	0
Nemophilia insignis . . . . . „	40	0	0
„ discoidalis . . . . . per gal.	1	1	0
Stock, scarlet, 10 week Stock . . . per cwt.	20	0	0
Lupines, of sorts . . . . . per bush.	1	0	0
Gilia tricolor . . . . . per cwt.	12	12	0
Aster, fine mixed German, 16 varieties, mixed „	20	0	0

And all other kinds of seeds, too numerous to insert, at equally low prices.

The above prices are for cash only. Catalogues are now ready, and can be had on application as above.

BEECHWOOD MELON.—"MUMBY WHEAT."

H. SILVERLOCK has to offer packets containing Six Seeds of this Melon at 2s. 6d., and 40 grains of the Wheat, at the same price per packet. They will be forwarded by post, free, on receipt of an order for 5s.—Mumby, Chichester.

FINE STRONG PLANTS OF SUPERB SEEDLING CINERARIAS, all well trussed, and forward for Winter and Spring Flowering, saved from the very best Blues and other fine choice named varieties, at 4s., 6s., and 12s. per doz. Packets of ANAGALLIS BREWERII & SUPERB CINERARIA SEED, 2s. 6d. each.—Applications, including post-office orders or stamps, will be immediately and carefully executed. Direct to MICHAEL BARNES, Senior, Nurserymen, Cambridge.

NAPOLEONA IMPERIALIS.—A few Plants of this beautiful Shrub, lately described by Dr. Lindley, in the "BOTANICAL REGISTER," may be purchased, price Five Guineas each, by application to Messrs. THOS. GIBBS and Co., the Seedsmen to the Royal Agricultural Society of England, corner of Half Moon-street, Piccadilly, London.

ADDRESS TO THE PLANTERS OF ENGLAND.

TRUE HIGHLAND PINE-TREE.

MY LORDS, LADIES, AND GENTLEMEN,—The time has come when all those who have waste lands at their disposal should plant them. Of this I am fully persuaded, and I beg you will allow me to explain on what grounds this opinion is founded. England, generally, is a thickly-wooded country yet, strange though it may appear, it has not been planted with any view to meet its most urgent wants. If the poor farmer require an outhouse built for his cattle, he cannot have it because there is no deal-wood in the neighbourhood: he builds it therefore of whins, or of any other rubbish he can lay hold of. Instead of having plenty of fir-wood on all hands to fence young hedges, planted like other things on the common surface of the ground, military-like fortifications have been raised to divide fields, occupying as much good land as is contained in three of the largest counties of Britain: it is on those banks ineffectual attempts have been made to grow hedges. After the 1st of March, when the Royal Agricultural Society's Prize on fences shall have been awarded, a great proportion of the hedges throughout England will be reconstructed by planting them on the plain surface; and the question will then arise, "Where is the wood to protect them in their young state to come from?" Turning to the railways which are now being formed in every county in England, another and greater question arises as to the supply of wood which will be required in *their* construction. Go up, I am told, to the Lebanons of our island—those immense forests in the north of Scotland—and there hew down as many trees as will be required. From those, however, I find we must expect but a limited supply. Like the famous Mount of old, they are already overrun with the axe, and a continuance of the present rate of demand for a few years more will reduce the trees upon them to a mere remnant. It is not the original numbers required for sleepers which will effect this change, but it is the incessant demand, *ad infinitum*, for timber to replace that which is already laid down, or may be for the future laid down in additional lines. Look at it how we may, the state of our country at the present crisis prov s that our immense and almost measureless tracts of what is generally called waste land were not created to be a scene merely of unproductive solitude. The rains with which they are refreshed, and the fostering sunshine that rests upon them, might have taught us that Providence had designed them to contribute in some way or other to the wants of man; and though Nature has been unable to lead us to comprehend her lesson, so simply brought before us, necessity has at length compelled us to look to those districts where only a sufficient quantity of timber can be raised to meet our increasing wants. Now, then, is the time to plant: wherever there is a waste piece of ground, moor, or mountain, let it be forthwith invested with trees, for every year, for many years to come, will unquestionably bring with it an additional demand for timber. Thus far on the necessity of planting. Allow me next to bring under notice the sort of tree I would recommend to be planted, which is the chief aim of this Address. That tree is the TRUE HIGHLAND PINE, for introducing which, I had the honour, along with my brother, of receiving the Highland Society's prize. It is admirably fitted, in every respect, to take possession of all the uplands throughout England. It will grow freely on all soils suitable for the common Pine; its wood is very durable; and for railway sleepers it is unrivalled. Brindley, the celebrated engineer, considered its durability equal to that of the Oak; and Dr. Smith states, in the *Transactions of the Highland Society of Scotland*, that he has seen some of it taken down after it had been 300 years in the roof of an old castle, as fresh and full of resin, as newly imported timber from Memel, and that it was actually worked up into new furniture. "Such," says Loudon, "is the durability of this wood, that while the bog timber of the Birch is often found reduced to a pulp, and the Oak cracks into splinters as it dries, the heart of this Pine remains fresh, embalmed in its own turpentine."

MY LORDS, LADIES, AND GENTLEMEN,—Allow me to add a word or two on the merits of this tree as a landscape ornament. In this respect it rivals, if not excels, the Cedar of Lebanon. It has, at any rate, a much better ramification than the Cedar; for, as Sir Walter Scott observes, it assumes in a great measure the bold and contorted figure of the Oak. In illustrating the feats of Norfolk (and the remark is applicable to all England), it frequently occurred to me that advantage had not been taken of prominent situations by investing them with grand evergreen trees; for so soon as November comes, our parks lose almost all that weight of grandeur for which they are so celebrated in summer-time. Their solemnity ceases with the fall of the leaf; but were they ornamented with this Pine, its broad umbrageous canopy remaining green during winter, the change consequent upon the approach of winter would be much less observed, and our country residences would at all times be surrounded with the dignified accompaniments so consistent with their character.

The importance of this subject will, I doubt not, be accepted as an apology for my thus venturing to express my opinions so plainly on matters of English practice. My suggestion as to the improvement of park and pleasure-ground scenery by introducing the Pine in question is offered with the greatest deference, being fully persuaded that in matters of this description England has been always distinguished for its refined taste. I am ready to dispose of the Highland Pines at the following prices:—

Single Plants, strong and well rooted . . . 6d. each.
Strong Plants, 18 to 20 inches high . . . 5s. per 100.
Strong Plants, 15 to 18 inches . . . . 30s. p. 1000.
Smaller-sized Plants for exposed situations 10s. to 20s. p. 1000.

I have the honour to be, My Lords, Ladies, and Gentlemen, Your most humble Servant,
JAMES GRIGOR, NURSERYMAN, Norwich.

PERFECTION IN PEAS.—FRASER'S SHANLEY MARROW.

F. FRASER, NURSERY and SEEDSMAN, Lea Bridge-road, Essex, in offering his friends and the public the above Pea begs to assure them it has no rival, its quality being so far superior to Knight's and all other Marrows as those surpass the commoner Peas. Its height is about 5 feet, a prodigious bearer, and continues in season much longer than the usual kinds. The stock on hand is very limited. Price 7s. 6d. per quart. A remittance expected to accompany orders from unknown correspondents.

WILLIAM MAY [illegible] very moderate scale [illegible] may be had.

200 Hardy Shrubs and Climbers, in 100 sorts, for 21s.;
200 do. do., in 100 sorts, for 42s.;
200 sorts showy Hardy [illegible], 21s.;
200 do. do., do., 42s.;
100 Roses in 50 good sorts, [illegible] sorts, 42s.; 50 do. do. [illegible] sorts, 30s.
100 select Double Hollyhocks, [illegible] named, for shows, 21s.;
100 Gooseberries, [illegible] do., in 100 fine [illegible], 21s.;
Seeds of Hollyhocks, [illegible] 2s. 6d.; 500 seeds, 5s. each.
Seeds of Pansies, from first named sorts of last season's growth, 1s. 6d. and 2s. 6d. each [1000s post free].
Forest and Fruit Trees, Greenhouse and Stove Plants, [illegible] Flowers, Garden Flower Seeds, &c., comprising every department of the leading novelties in present cultivation.

Hope Nursery, Bedale, Dec. 1844.

HUNT'S IMPROVED HYACINTH GLASS SUPPORT, from 1s. 6d. each. The largest Assortment of Patent and other Garden-pots and Stands, from 6d. to 150s. per dozen, in Wedgewood's and other warranted Drawing-rooms, &c.—29, Queen's-row, Pimlico.

CORNISH KIDNEY POTATOES.—THE EARLIEST OF ALL EARLY POTATOES.—It is remarkable that this valuable sort should be so little known and cultivated in England. It is grown to some extent in the West of Cornwall, AND HAS BEEN PRODUCED IN THE OPEN GROUND DURING THE LAST TEN YEARS, FROM THE 18TH to the 30TH of MAY, (on an average.)

Upwards of three hundred acres are annually grown in the neighbourhood of Penzance, and thousands of baskets are sent, by steamers, to supply the London and Bristol Markets.

The growers obtain them so early, that they are enabled to procure an excellent second crop on the same land.

It is a most valuable sort, and should be grown in every garden where early vegetables are required.

Sold in Hampers, containing 7 and 14 gallons, at 5s. and 9s. each, package and carriage free to London or Bristol, which will be forwarded on receiving a Post-office order, on application to WILLIAM E. RENDLE, Union-road Nursery, Plymouth, December 21, 1844.

HERTFORD NURSERIES.

E. P. FRANCIS having received various Testimonials from Gentlemen, &c., as to the excellence and superiority of SNOW'S WINTER WHITE BROCOLI, advertised in the *Chronicle* last season, begs now to inform the Nobility, Gentry, and Public, that Supplies obtained of the Hertford Nurseries, Messrs. Notts, 152, Fenchurch-street, Messrs. Wrench, London-bridge, and Messrs. Hannay, Marylebone, House-street, at 2s. 6d. per oz.

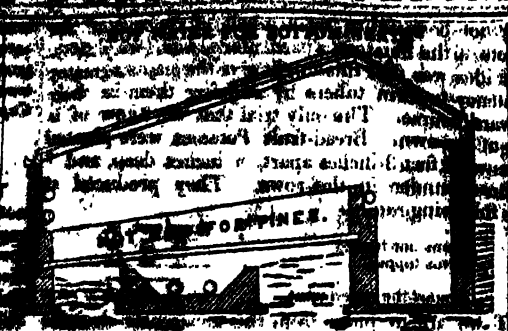
E. P. F. begs further to recommend to those persons, who have not yet obtained it, SNOW'S HARDY MATCHLESS GREEN COS LETTUCE, which has been proved by several Gentlemen to be superior in flavour and sweetness to any other Lettuce known, very crisp, very hardy, requires no tying up, and is fit for use three weeks earlier than the common Green Cos; in sealed Packets, 1s. 6d. each.

E. P. F. has also received from *Mr. Snow* a few Packets of his HORTICULTURAL PRIZE CUCUMBER, each Packet containing 7 seeds, 2s. 6d. per Packet; also a small quantity of his very fine CHINESE PRIMROSE, of the white and purple kinds, and all saved from beautiful fringed varieties, in Packets, 2s. each.—Dec. 7, 1844.

WHITNEY'S PATENT CLOTH for COVERING GREEN-HOUSES, CUCUMBER, or MELON PITS, &c. This Cloth is strongly recommended for the purpose of applying Whitney's Composition upon, and is much more durable than any other material; when coated it is beautifully white and transparent. The perfect success of Whitney's Composition for all Horticultural purposes cannot be more fully established than by stating, that on the 1st of April last, a Black Hamburgh Vine was set in a border, the stem introduced into a house covered with Calico, and brushed with Composition. On the 1st of Sept. a bunch of Grapes was cut weighing 10½ ounces, the fruit was finely coloured, and the flavour pronounced to be excellent. A sample was sent up to the Editor of the *Gardeners' Chronicle* for his inspection. The tree grew very luxuriantly, the foliage very fine, and the wood ripened exceedingly well. As a winter protection it is infinitely warmer than glass.

The PATENT CLOTH and COMPOSITION can be obtained of Messrs. Butler & Muckley, Covent Garden Market; Hurst & M'Millen, Cockspur-street; Warner & Watson, Cornhill; Barclay & Sons, Farringdon Street; and Hannay & Co., Oxford street. Wholesale and Shipping Agents, Mr. Bailey, Wolverhampton.

SLATE WORKS, ISLEWORTH, MIDDLESEX.



THE following Articles, manufactured in Slate, for Horticultural purposes, may be seen in use at Worton Cottage, upon application to the Gardener (Sundays excepted):

Tank Covers — Coverings for Pinnies.
Cisterns — Coverings for Pits and Verandahs.
Shelves — Orchard-house Shelves.
Garden Edging — Flower Boxes, &c.

EDWARD BECK will be happy to [illegible] personally or by post.

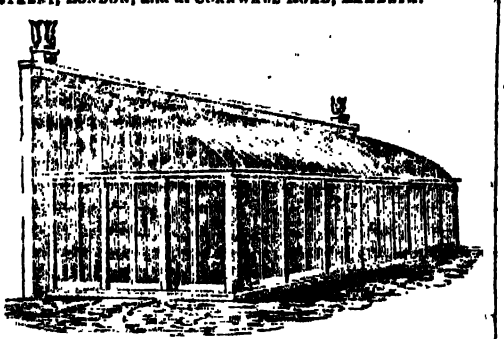
TANNER'S VITREOUS COATED [illegible] TUTE for GLASS for HORTICULTURAL and other PURPOSES. The above recommends itself to the Horticultural Florist and Horticulturists, as producing effects superior to Glass at half the expense. The support the Proprietor has received from many highly respectable Florists encourages him to hope that his labours have not been misapplied in bringing before the public an article so generally required. Sizes of glass, 7-8ths of a yard wide, thin, 2s. 6d. per yard; stout, 3s.; 1 yard wide, 2s. 6d. Price of Fluid (for renewing the cloth after lengthened service), 4s. 6d. and 9s. 6d. per bottle. Manufactured only by N. W. TANNER, Chemist, Exeter, and Sold by Messrs. Butler and Muckley, Covent-garden, London; Mr. Cunningham, Paradise-street, Liverpool; Messrs. Lucombe and Pince, Exeter Nursery.

LAND TO LET.—Most desirable, and important opening to those now engaged in the Nursery Garden Business, or who have a knowledge of it. FROM TWENTY to NINE or more ACRES of LAND, where the soils are peculiarly suited for the purpose, and in a most eligible situation, close to the suburbs of Ipswich, may be hired at a moderate Rent, there being now no Nursery Grounds anywhere near Ipswich, except on a very limited scale. All the Land may be had at once, or it may be taken by degrees. The character and qualification of any proposed tenant would be strictly examined. If requested (probably) the assistance of some capital might be given; and also that of an industrious and prudent Partner, with Capital, as well as other advantages.—Apply to Mr. E. HARVEY, Tower Church Yard, Ipswich.

WEEKS AND DAY, ARCHITECTS, &c., Clock Place, Eim's Road, Chelsea, HORTICULTURAL [illegible] Hot-water Apparatus Manufacturers, invite the attention of Horticulturists to their improved Plan of Hot-water Heat, now becoming so universally adopted.

From the extensive Practice they have been honoured with for 20 years in designing and building CONSERVATORIES, GREENHOUSES, HOTHOUSES, PITS, &c. &c., and erecting their HOT WATER APPARATUS to every description of Buildings to which heat is applicable, J. WEEKS AND DAY have the greatest confidence in recommending their BOILERS as the most efficient of any yet invented, their largest being capable of heating a range of Forcing Houses 300 feet in length, with a comparatively small quantity of fuel, and only requiring attention once in 10 hours. To be seen in use at most of the London Nurseries, also at their Manufactory; and a variety of Horticultural Erections, Models, Plans, &c. &c.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.



D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.

D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

COTTAM AND HALLEN, ENGINEERS, IRON-FOUNDERS, &c., &c., No. 2, WINSLEY-STREET, OXFORD-STREET, LONDON, and at CORNWALL ROAD, LAMBETH.

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principle, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public or Private Buildings, &c., with COTTAM'S PATENT OR ROGERS'S BOILERS. After 15 years' experience, and having fixed upwards of 2000 Apparatus for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale.

Materials may be had for those who wish to fix their own Apparatus.

THE TANK SYSTEM on an improved principle; that will heat the house at the same time, without pipes.

IRON HURDLES, best Wire for Strained Fencing, Ornamental Iron and Wire-work, Garden Chairs, &c. &c., and every description of Implements for AGRICULTURAL and HORTICULTURAL PURPOSES.

[illegible] Stoves at their Manufactory, 9, Winsley-street, Oxford-street, where a large assortment of the above may be seen.

STEPHENSON AND CO., 61, Gracechurch-street, London, and 17, New Park-street, Southwark, Inventors and Manufacturers of the improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully call the attention of Horticulturists to their much approved method of applying the Tank system to Hothouses, Conservatories, &c., by which atmospheric heat is given at bottom, and is diffused to any required degree without the aid of pipes or flues. S. & Co. have also to state, that the system of numerous friends have now making their Boilers of iron as well as Copper, by which the cost is reduced. These Boilers, which are now in use, however, scarcely require description, hence those who have not seen them, upon inspection, prospectuses will be forwarded as well as reference of the highest authority, or they may be seen in front of the Nobility's seats and principal Nurseries throughout the kingdom.

S. & Co. beg to inform the Trade that at their Manufactory in New York, every article required for the construction of Horticultural Buildings, as well as for heating them, may be obtained upon the most advantageous terms.

Conservatories, &c. of Iron or Wood, erected upon the most ornamental designs. Balconies, Palisading, Field, and Garden Fences, Wire Work, &c. &c.

HEATING APPARATUS.—[illegible] to announce that, in addition to the many [illegible] for which Galvanized Iron is peculiarly [illegible] Tanks and Gutter for [illegible] Bottom-heat, Conservatories, &c. &c., P. has also to state that, having secured the [illegible] of parties of the greatest skill and [illegible] Plans and Estimates for Heating and Ventilating [illegible] Buildings, Public Edifices, [illegible] Factories, &c., accompanied by references to works. P. does not profess [illegible] any one particular form of Boiler as the best, to the exclusion of [illegible] but considers that [illegible] requires peculiar [illegible] and arrangements, and engages to work [illegible] Apparatus [illegible] Galvanized Iron, Sheet Copper, Cast Iron, Wrought Iron, &c. &c. [illegible] Manufactory, Bridge Wharf, Battersea, [illegible] to the Trade.

GUTTA PERCHA PERUVIA M.S. COLLEGIAN) [illegible] BY THEIR GREAT LONDON AGENTS, GIBBS, BRIGHT, & CO., LIVERPOOL AND BRISTOL, 47, LIME-STREET, LONDON, &c. &c.

[illegible] ENGLAND INDEPENDENT OF THE WORLD FOR COTTON.

THE Attention of the Agricultural Interest, at this momentous crisis, is directed to the great importance of LIQUID MANURE, and the best [illegible] which it may be appropriated, by the most [illegible] for the purpose, either portable or fixed. Garden Engine, and Barge Pumps; also those for Distillers, Brewers, Soap-boilers, and Tanners, for hot and cold [illegible] Barrows kept for hire, for Excavations and Wells. Portable Steam Engines of any Power, for Horticulture, and every [illegible]

The Trade supplied on advantageous terms by BENJAMIN FOWLER, Engineer, &c. &c., Derby Road, Bow Common, London.

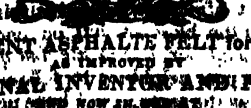
IMPROVED ROOFING FELT.

McKIBBIE'S PATENT ROOFING [illegible] is particularly applicable as a Substitute for Slates, Tiles, Thatch, and other articles used for Roofing, from its Economy, Durability, and Lightness. It is quite impervious to wet and damp, resists the heat of the sun, and is a [illegible] conductor of heat or cold. Besides the economy in repairs, the timber where it is used may be so [illegible] as to save its whole expense. It requires no other coating, and by attention to printed directions may be applied by a common labourer. It is free from breakage and contraction, [illegible] and requires neither painting nor coating. It is now in very general use for Roofing Houses, Verandahs, Sheds, Workshops, Stables, Railway Stations, Icehouses, &c. &c., and for protecting Plants, covering Garden Frames, Corn, and Hay Ricks, the [illegible] sides of Sheep-folds; and to Engineers it [illegible] a cheap, warm, durable, and portable Roof [illegible]

This [illegible] Roofing is much more durable than the common Felt, made in [illegible] for the same purpose, like it or other [illegible] and being [illegible] it [illegible] cannot percolate through the nail holes. [illegible]

Sold in Sheets, 28 inches [illegible] 2s. 6d. per square of 100 [illegible] new [illegible] Apply to H. C. BOWRING, [illegible] No. 12, East India Chambers, Leadenhall-street, London.

CHEAP AND DURABLE ROOFING.



BY HER [illegible] ROYAL LETTERS PATENT

TO GARDENERS, NURSERYMEN, AND OTHERS.

F. M'NEILL & CO., of Lamb's Buildings, Bunhill-row, London, Manufacturers, and only Patentees of IMPROVED PATENT ASPHALTED FELT, for Roofing Houses, Sheds, Verandahs, &c., and for Protecting Plants, and Covering Garden Frames, beg to call the attention of Gardeners and others to their superior article, which has been exhibited at the Great Agricultural Shows of England, Scotland, and Ireland, and OBTAINED the PRIZE for being the best and cheapest article for roofing, &c. It has been tested in the gardens of several noblemen and gentlemen in the neighbourhood of London, and in different parts of the country, to whom reference can be made. The Felt is impervious to rain, snow, and frost, and a non-conductor of heat and cold. Its advantages are Lightness, Warmth, Durability, and Economy.—Price ONLY ONE PENNY PER SQUARE FOOT.

Samples, with directions for laying on, and testimonials as to its merits, sent free to any part of the country.—Patent Felt Works, Lamb's Building, Bunhill-row, London.

THE BEST AND MOST DURABLE ROOFING, FOR BUILDING AND GARDEN PURPOSES.

By Royal Letters Patent.

THE PATENT ASPHALTE FELT for ROOFING, as [illegible] PROVED BY

THE ORIGINAL INVENTOR AND PATENTEE,

THE ROYAL HORTICULTURAL SOCIETY'S GARDENS AT CHISWICK.

To be had only of [illegible] to

THOS. JOHN CROGGON, 2, INGRAM-COURT, FENCHURCH-STREET, LONDON.

The above Material has been used and approved of by the Nobility, Gentry, and Agriculturists generally, as a ROOFING and COVERING to SIDES of FARM BUILDINGS.

Its advantages are—The Felt is perfectly impervious to rain, snow, and frost, and being a non-conductor, it has been proved an efficient PROTECTIVE MATERIAL TO PLANTS.

The price of the Felt is ONLY ONE PENNY PER SQUARE FOOT, being much less than half the expense of Slates, Tiles, &c., and from its LIGHTNESS, WARMTH, and CHEAPNESS is particularly well suited for Hothouses, &c. A discount allowed to the Trade. THOS. JOHN CROGGON, 2, Ingram-court, Fenchurch-street, London.

Patent Asphalte Felt Works, Dec. 21, 1844.

THE FILBY RASPBERRY.—On or about July 7th, 1843, Mr Henry Youell came to the garden [illegible] requested me to give him some fruit of the above [illegible] send to Dr Lindley. Mr. H. Youell subsequently [illegible] over the Garden, and gathered several [illegible] dozen would be sufficient. He then consulted [illegible] best way of packing them, and I recommended [illegible] them in cotton wadding or wool [illegible] that he thought it would be the best suitable, [illegible]

Signed, Wheeler Gaze, [illegible]
Filby, Dec. 10, 1844. Filby, near Yarmouth, Norfolk.

LANDSCAPE GARDENING AND [illegible]

MR. GLENDINNING, after [illegible] Metropolis, has had the honour to be [illegible] number of Noblemen and Gentlemen [illegible] their Parks and Gardens, and [illegible] of Horticultural Buildings [illegible] effectual manner. He has many years' practical knowledge in these important subjects, and Noblemen and Gentlemen desirous of consulting him, are respectfully requested to address him at Chiswick Nursery, near Kensington.

The Gardeners' Chronicle.

SATURDAY, DECEMBER 7, 1844.

MEETING FOR [illegible]
Parent, Bee a Scientist [illegible]

THE next point in Dutch culture, which the experiments before us were intended to elucidate, is the effect upon the crop of removing the blossoms As the reasons for this operation have been already given at p. 427 of the present Volume, we need not repeat them here. The results are all that we need occupy ourselves with.

Our own opinion was in favour of the operation; and upon the whole, we think that the new evidence before us confirms the correctness of our views. "Falcon" says, "I have no doubt, from experiment, that taking off blossoms, *at a proper time*, is an advantage It should, however, be so done, as not to give the plants an opportunity of throwing out fresh flowers, which will exhaust the tubers; the best time is just before the formation of seed vessels. If the flowers are taken off too soon, the plants may exert themselves to produce them before *the tubers are strong enough to consume the extra nourishment provided by the destruction of the blossoms.*" This is sound good sense, and [illegible] it may account for some statements adverse to the inferences drawn from [illegible] "Falcon."

A gentleman [illegible] the following result

[illegible]

This experiment, [illegible] at first sight seem to show that taking off the blossoms is actually prejudicial, for the greatest weight was obtained from Nos 1 and 5, in which the flowers were left on; but it is to be remembered that they were *outside rows*, and therefore must be left out of consideration. Of the inside rows, which alone can be justly compared with each other, the greatest [illegible] 2, in which the flowers were removed. That this conclusion is nullified by [illegible] which the crop was the same as when the flowers were left on; but we cannot receive such an instance, especially in an experiment conducted on so small a scale, as conclusive against the practice. More so is a statement by "F. H. S," who says, "I caused all my Potatoes to have the flowers removed—reserving, however, one row as a means of comparison, which was allowed to bloom. On lately taking up the whole, I had this single row, with one on either side of it, weighed and measured, and we were unable to perceive any difference, either in point of weight or quality, in the three rows thus compared. They were all of the same description, and planted at the same time."

In opposition to this is the following statement, by "J. W.," a correspondent near Romsey:—

"Having followed your recommendation, of taking off the flowers of the Potato when in blossom, I wish to add my testimony to the advantage derived from doing so, by assuring you that the crop of Potatoes far exceeded that of former years, both in size and quantity. I had the blossoms left on one row, and *the crop was very inferior, both in size and quantity.* I prevailed upon a poor neighbour to follow the plan, and the result was the same; and I hope next year to induce others to try it."

This is all the information we have received upon this point of Potato cultivation. It is much to be regretted that the experiments were not made upon a larger scale, and the results, in some instances, reported with more exactness. At present we see no reason to alter our expressed opinion, that pinching off the Potato flower is a considerable advantage. May we hope that some intelligent cultivators will put the question to rest another year, by trying the experiment comparatively on a larger scale, and furnishing us with the actual weights they may obtain?

'Connected with this subject is another that we pointed out as worth inquiry, namely: whether it may not be useful to top or [illegible] shoots of the Potato at a particular [illegible] The idea was that this might give the plant [illegible] sufficiency to form tubers by stopping them in [illegible] upward course The only trial that we know of is [illegible] own Bread-fruit Potatoes were [illegible] in rows 2 feet 3 inches apart, 6 inches deep, and [illegible] inches under in the rows. They produced as the following ratios:—

Stems not topped	12
Stems topped	17

[illegible] the experiment

If we are to judge from this apparently decisive result, the experiment is not worth repeating. But the following trial goes the other way.

Bread-fruit Potatoes were planted singly 2 feet by 2 inches apart each way Their produce was on this rate:—

	tons.	cwt	lb.
Stems topped	5	6	56
Stems not topped	4	1	0
In favour of the experiment	1	5	56

Now, from this we infer that when the Potato plant grows extremely vigorously, topping is a decided advantage, and the reverse when it grows slowly This year the Potatoes, on the land where the experiment was tried, suffered much from drought; were, by it, checked more than enough, and topping became prejudicial by adding to the mischief But where, from having a great deal of room to grow, the effect of the drought was hardly felt, and the haulm became very strong, topping produced the result that was looked for in the remarks made at p 293 If, then, in a dry year like this, it proved advantageous, under any circumstances, how much more may be expected from it in our ordinary rainy summers!

We therefore submit that the question is not determined adversely to our anticipations, but that the probability of Potato topping being a good system is so much increased as to render it worthy of more extended inquiry, whenever, and from whatever cause, the Potato haulm is very rank

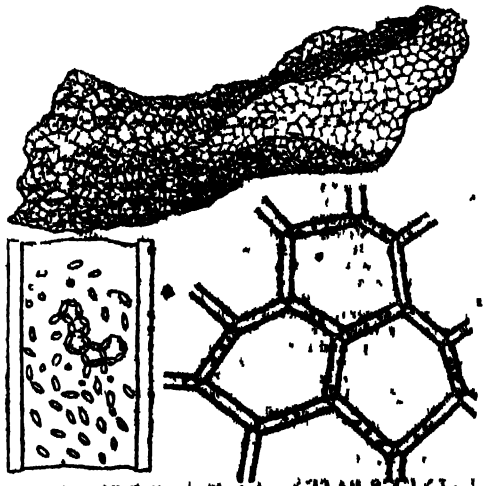
By the kindness of a friend we have been supplied with information relative to the Heaviest Gooseberry of 1843 It weighed 25 pennyweights, was the "Roaring Lion," and was grown by Mr. Fardon, of Woodstock Therefore, our Nottingham friend, Mr T. Gibson, still retains the "championship" of Gooseberry growing

NEW METHOD OF GROWING THE MUSHROOM (*Agaricus campestris*).

PASSING over the various modes of forming or making the beds, which I consider to be of minor importance, I proceed to direct attention to the failures which afterward take place, and which so frequently disappoint previous expectations. The principal cause of these failures I attribute to the very imperfect methods of supplying water to the beds which are in action.

The principal requisites for the successful culture of the Mushroom are heat, light, air, and a damp atmosphere In the first place, with me, the dung is collected fresh from the stables, particularly from horses that are fed upon dry food, such as corn and hay. It is thrown into a shed to dry, a little before it is made into beds, my boxes are trellised at the bottom, which allows the heated air to penetrate through the mass of dung easily, a little hay or rough litter is spread over the bottom of the box, in order to prevent the dung from passing through the trellis work, and every two or three inches of dung that is added is beaten hard with a wooden mallet, until the layers reach within 1½ inch of the top of the box. As soon as the heat of the dung falls to a proper temperature, I insert large pieces of spawn into the bed at the distance of about eight inches square. I rarely make use of spawn less than 12 months old, and the less that it is broken I find that it produces the better crops.

In about a week or 10 days afterwards, I finish off the beds with green turf 1½ inch in thickness, making the beds in my boxes in all about 9 inches in depth. I beat down the turf very firmly with the back of a spade in finishing; afterwards I have no farther trouble, except in paying attention to the fire, and in admitting fresh air as it may be required. The house is heated by open tanks, which run through the centre of it, and which return again into the boiler, giving out a sufficient quantity of moisture for the necessary development and growth of the Mushroom. During night the Grassy turf becomes copiously beaded with moisture, and should the following day prove fine, I never omit giving admission of fresh air by the door-way. The temperature of the house ranges from 60° to 65° during the day, and at night it is frequently allowed to fall as low as [illegible]



The great advantage of growing the Mushroom upon fresh Grassy turf is obvious to any one accustomed to its cultivation. I have been in the habit of growing it, and with great success, upon coal refuse for the last two years, and at present I have two boxes at work, one covered with coal-dust, the other with turf; the produce of these shows the relative advantages of the two methods, for although those from the coal-dust are large and of good flavour, they are decidedly inferior in both respects to those produced by the Grass-covered beds; indeed, such is the superiority of the latter, that if the Mushrooms [illegible] both beds were gathered and mixed indiscriminately, any one would, without difficulty, select those grown upon the turf from those raised on the beds [illegible] the small coal.—*John Hamilton, Gardener to Capt. Mitford.*

[illegible] OF PLANTS.—No. VIII.

[illegible] which form the subject of the present [illegible] with the fruit moulds (Mucor) in having the [illegible] organs contained within a vesicle, either [illegible] the joints of the stem or springing [illegible] of it. This vesicle, however, differs materially in being usually composed of a number of minute [illegible] which [illegible] to a [illegible] Above all, in the curious fact that a new individual is produced within it immersed in gelatine, which, when its envelope bursts, increases gradually till it attains the [illegible] of the parent plant. This is a mode of fructification analogous to that of the curious fresh-water Alga called Hydrodictyon, which resembles a netted purse, at first closed, but at length open at either end; the tubes, of which the meshes are composed, at first contain a mass of granules, which, in process of time, are, by some mysterious law, disposed in pentagons and become grafted to each other by their extremities, and then increasing gradually burst the general envelope, each joint of the original net thus giving rise to a new one.

Antennaria Robillardi.

1 Portion of full grown plant.
2 Portion of a joint in which the [illegible] to dispose themselves in pentagons, the [illegible] of the new plant.

But not only is the plant rapidly increased by this ready formed race of new individuals, but every portion of the thread easily vegetates, and even the little cells of which the wall of the fructifying cyst is composed are themselves also viviparous, and hence these parasites overrun with their black soot-like, or woolly masses, the leaves and shoots of such trees and shrubs as are subject to their attacks. In some species the threads form little more than a black velvety down, covering principally the young shoots, disfiguring and very materially injuring them; in others they produce a cloth-like felt, completely investing the whole plant, and in one case the threads are much elongated, and anastomose so as to form a black spongy mass. They exist in various parts of the world. In Scotland young Pines are very subject to be attacked by Antennaria pinophila. In Perthshire especially they have been observed to be much injured by it. In the South of Europe the arboreal Heaths and Cistuses are frequently covered in consequence with a dense black coat. One species, which is figured above, runs over the fronds of Ferns in Juan Fernandez; Mr. Gardner gathered a species investing trees in Brazil, and in the Antarctic Expedition Dr. Hooker observed one very general, on the species of Dracophyllum, especially D. *latifolium*, and the same species apparently has been gathered in the Swan River district of Australia, and in South America. All alike prove injurious, by clogging up the stomates and veiling the young shoots and leaves from the influence of light, which is so essential to the health of vegetables. In a specimen from Perthshire, sent by a gentleman of the name of Drummond to Sir W. J. Hooker, in 1840, and submitted to me, I find other parasites intermixed, but all of nearly the same colour and producing the same injury.

The dark olive-green coat, which is so common upon Orange-trees in Madeira, and which may be observed also on them and other plants in our conservatories, and on various trees, especially Plum and Lime, in the open air, must not be confounded with the Antennariæ, being of a very different construction, however similar in appearance. Of this we shall have to speak when we come to the Mucedines. The productions now before us do not, it would seem, like them, spring from any glutinous deposit on the leaves or stems, as is the case with the mould of Plum-leaves. At least, nothing

of this kind has been observed at present. Those who have an opportunity of observing the parasite on young Pines, from its first appearance, would do a service to science by recording their observations, without which it is impossible to suggest any remedy.

One or two allied genera occur in tropical countries, which have precisely the same habit, but they are not of sufficient importance to demand our attention here.—*M. J. B.*

BREWING.

Having observed several inquiries respecting brewing, the answers to which appear to me to be very far of the mark, and thinking that a mode which I have practised without a single failure for many years, and all through the summer, even in the hottest weather, may be usefully made known to those who are beginning, I am induced to send it; premising that the process is well known in Berkshire and no doubt in many other counties; and that, although I am well acquainted with the practice occasionally of the general method of brewing by cooling and working with yeast, using what I do not, I use the thermometer and saccharometer,—in the mode I am now about to recommend, I dispense with both those instruments, with the coolers, and with the working tubs, and the beer is made and casked all in one day; in short, this mode is commonly called "brewing red hot." But first, let me tell the "Farmer's Daughter," and all others, that two things are indispensable to the process; and the first is, that the copper, mash-tub, under-back, and casks, should all be as clean as a milk-pail or a wine decanter; and secondly, that it is useless to attempt brewing in any way, if the cellar is not of a tolerably even temperature, say from 45° to 60°; if it rises above the latter in summer, it is of no use to brew, for the beer will not keep.

I will suppose, then, that the brewer has three 18 gallon casks (for I am going upon a very small scale); send one to the best public brewer who may live conveniently near, to be filled with good clear beer of moderate strength; this will cost from 15*s.* to 18*s.* Get from a first-rate maltster, 3 bushels of best pale malt, ready ground, and 3 lbs. of the best Farnham Hops (and here I may say that, according to taste, the Hops for each bushel of malt may vary from half a pound to two pounds). Boil the water (soft, if you have it clean, but if not, rain water) and put it into the mash-tub; wait ten minutes, and put in the malt; mash it well in the usual way, cover it up, and let it remain four hours; before you draw it off, have in some vessel near, a copper-full or two of water, briskly boiling; draw off the first wort, and put it into the copper with the Hops, and set it boiling; then take a clean watering-pot, dip out the hot water that is handy, and water the grains in the mash-tub, keeping the mash-tub tap running till you have sufficient to fill up the copper; this draws the grains as effectually as three mashes, if well done, and it should be very gradually, and take half an hour at least; the copper must then be watched till it beats pure, as the brewers call it; half an hour and a half; rake out the fire, draw from the cask of beer one-third, and put it into one of the other barrels, and another third into the second—you need not be very nice about the exact quantity; thus, each cask will be one-third full. Then, I need hardly say, very carefully put the hot liquor, Hops and all, stirring it up, that the Hops may be equally divided, into the casks, and your brewing is done. You will, however, have kept back enough to fill the casks, as the liquor sinks in them from evaporation, and about two gallons in a large pitcher, to fill up for three weeks or a month, because the fermentation will be more like that of wine, than beer in the usual way, and is sometimes so slight, as to be hardly perceptible: you may tap it at the end of a month. When the first cask is empty, clean it well out; draw off three gallons of the second cask, and brew another bushel of malt, as before; and so on brewing a bushel at a time.

Now, the principle of this process is, that the old beer supplies the place of the yeast; some people run upon ground malt and the hot liquor into an empty cask, in which case it is longer in coming round, for want of fermentation, but is equally good. When brewed very strong, this sort of beer is apt to be rather heady; but I prescribe for the working-man, who wants no strong beer. Of course, the process must vary much, according to the size of the copper and other circumstances, to suit individual case, which one set of directions cannot embrace. If the copper is very small, there must be two or three mashes (the first two or three liquors only of the one mash which I recommend, and the grains watered with the watering-pot. In conclusion, this process suits the honest, hard-working peasant, who cannot afford the dawdling process of the small brewer, to brew his own beer.—*T., T. C. G., Oxford.*

THE ROSE-GARDEN.

(*List of Roses continued from page 837.*)

STANDARD AND DWARF.

Hybrid de Luxembourg, Chair's Pour Surprise, Triomphe d'Ange, Brown's Superb, Globe d'Or, Ville, Common Noisette, Scarlet Perpetual, Cloth, Comtesse Rouge, Holdist, Noisette pulchella, Lamarque, Reine des Surpasse, Reine d'Espagne, Rose de Rouelle.

Village Maid.—Growth formal, no scent, but delicate of slaty hue; singular.

Fringed Provins.—Growth as the Cabbage, but buds beautifully crested with moss.

Du Roi.—Well known to all.

Yellow China.—Long, oval, and singular in the bud; not always to be kept healthy.

Crimson elevate.—Scent fine, but much far from vigorous, and rather delicate.

Fallen Briar. Scarlet upon dull crimson.—A brilliant scarlet; this class, however, is, in many others, very uncertain in their growth, almost always requiring and from their natural habits of drying off early are amongst the most uncertain as to growing strong.

Hartisonii.—Colour bright yellow; appearance not commendable.

Bengale elegans.—Very old Rose, but profuse in flower, and vigorous.

Noisette Perlet. Celestial.—Delicate in colour, beautiful in shape, and by some held in the highest estimation; the wood is vigorous, and must be left very long in the shoot to insure flowers.

DWARFS—BEAUTIFUL BUT DELICATE.

To be worked on slight stems, those of a year's growth being preferable:—*Tea Hymène, Tea fraxinans, Tea gracilis, Tea viorata, Tea Hamon, Tayliani, Tea Lyonis, Tea Hardy, Tea Caroline, Rose de Siam, Tea Hardy.*

The six last new Roses, though in the writer's possession, have not been seen by him in flower, and he is not acquainted with their habits:—*Chromentella, La Reine, Charles Souchet, Comte de Rambuteau, Madame Souchet, Tea Devoniensis.*

The above List contains many Roses that have been but recently grown, as well as many that have been long cultivated. It has been the object of the writer to give the names of those which he admires most, without reference either to long standing or novelty; but amongst the large collections now made, there are very many desirable, though not here mentioned. The cultivator is recommended, therefore, to choose the periods of flowering, both in spring and autumn, to visit the best nurseries convenient to him, mark the trees he means to have (not merely ordering the plants to be sent), and be persuaded into buying none that he does not very much admire. By visiting several nurseries, he will be inclined to reject some Roses, which only rise in his estimation because a peculiarly favourable situation had given the plants unusual health and beauty, and choose others which had suffered in appearance from an opposite cause, but which he will find, on second examination, well worthy his best regard. He will get many hints he would not otherwise have obtained, and if he purchase with reference to real beauty only, whether of flower, foliage or growth, he will find his success satisfactory, and his outlay moderate. If novelty, uncombined with these advantages, form any part of his object, almost every nurseryman can, from time to time, add to his collection. He must not be disappointed if he find some of his Roses do not flower as well with him as elsewhere, very much depending upon the nature of the soil that supports them; he must, however, be careful as to one thing, which is, if his plants be placed on Grass, not to let the turf be put round them the first year, as it absorbs all the rain that falls, however much it may be, and starves the trees.

The advantages of free-growers are, that at almost every season they will afford buds fit for use, and many of them continue to bloom and look handsome till the end of autumn, and the number of shoots from a single bud are unlimited; thus forming a head the first season, and restoring the activity of the whole tree, in a short space of time. They are not, however, quite so easy to keep in order as the other sorts, and they are more apt, on first coming into leaf, to attract the aphides, that little terrible insect, the scourge of the Rose, and for which no adequate means of destruction is known; though destroying, by the hand, at the commencement of the season, is the most effectual means of keeping down. As it is not only incouvenient and tedious to make use of the fingers for the purpose, as well as difficult to remove the insects without crushing them upon the shoot, which invariably either retards or stops its growth, the readiest method is to brush them off with a common painter's brush, made of bristles, the hair of which viz. that part which is below the binding, is about an inch and a half long, and the same in circumference. Lay the shoot along the palm of the left hand, and pass the brush from the bottom of the infected part upwards, and with a very little practice you will be able to clear a plant of its tormentors, without injury either to the bloom or to the tenderest shoots to which the brush is applied, in a space of time which would at first appear impracticable.—*A. H. B.*

Home Correspondence.

Disease of the Larch.—Observing in the Chronicle (p. 796) some remarks by Mr. Barnhill, on the above subject, I would beg to inform him that in the month of March, 1841, I planted a number of Larches (Cathedral trees) which had been previously heeled in for a short time, and that many during their first year exhibited the symptoms he describes as produced by Rabbits, though none were to be seen on the same. These shoots were to be found on the lower branches of the Larch, depending from the side of the plantations. Observing the great destruction of the shoots, I shot one, and on examination discovered that it had been devouring these trees through little holes, which appeared to me to resemble very much the pinholes made by a pin. I have since many instances of the same kind. We have also a number of Larches in a plantation by themselves, which have not been touched.—*J. S.*

The Potato.—In the cultivation of the Potato, which has of late years become so prominently into notice, should not some reference be had to the elevation of the land on which the experiment is made? For instance, Stockton-on-Tees and Birmingham are situated very differently; the one is nearly on a level with the sea, the other 500 feet above it, I believe, and in the heart of England. Both these places have been quoted by you. I know that the difference of elevation of 50 or 60 feet does much to the human constitution.—*C. W.* [We attach no importance to this point, so far as the cultivation of the Potato is concerned.]

Liquid Guano.—Extract the guano, in the first instance, by steeping it in water. This will give liquid Mo. 1. Then add 1 per cent. of borax to the water in which it is steeped, and use the effect of that. If you attempt to manufacture, no one can be surprised.—*Timothy Puzzle, N. B.* You may use the borax at first, if you like.

Autumn planting Potatoes.—More than 20 years ago, I heard my labourers (in Ireland) talk of an old and general custom of their forefathers, of leaving the seed of the finest crop in the ground, and splitting with their spades the larger Potatoes when they were digging out the crop of the current year. It is a very common thing in Ireland to raise plants of Potatoes early till the ensuing spring, either from some unfortunate circumstance befalling the owner of them, or from their being so bad a crop as not to repay the trouble of digging. Now, personally speaking, these have more than a covering of four inches, and many of them not more than an inch, yet their suffering from frost has rather been the exception than the rule. In an agricultural survey of the county of Wexford, some years ago, it appeared there is a strip of land near the sea, in which they plant the White Kidney in the month of September, and supply the Dublin market with them in the month of May following. These are, however, treated with a double allowance of manure, and well covered—say with from four to six inches of the loose soil. In the county of Tipperary, 18 years ago, I planted Potatoes (whole ones, called Quarters), in September, and dug them in May, but the winter was very mild. I planted five or six years ago in Donegal, in the winter, Potato sets that had sprouted in the house (a warm room), preserving the sprouts on them, and began to dig them of very good size on the 18th June; the crop was a heavy one. In this country, where Potatoes occupy about one-third of the tillage lands, a furrow cannot be turned in spring without meeting with innumerable Potatoes, that have been all winter left in the ground, at a depth scarcely ever exceeding four inches, and very few of these are found injured by frost. I feel, therefore, assured that little danger is to be apprehended from frost in an autumnal planting, and especially where the seed is deeply buried, and this either in autumn or spring planting, the crop is more productive when deeply set. I would not, however, plant them deeper than six inches, lest, on the ground being dug, the frost acts more powerfully on wet, than on dry ground, yet I have no recollection of having found Potatoes suffer more in moist ground than in dry; but I do recollect, 20 years ago, at a time when a disease called the rot, prevailed very generally in the neighbourhood, and destroyed more than half of the Potatoes in the country, that I planted in the autumn some Potatoes in dry, and moist, might say wet ground; the sets in the former grounds all perished from the rot, while near half of those in the moist ground survived. I have frequently planted in the autumn and winter without suffering any by it, and I should never hesitate so to do. It is, no doubt, if possible, advisable to plant before the Potatoes are exhausted by growing out in the spring; but should this be unnecessarily delayed till late in the spring, I think improved seed might be obtained by burying the Potatoes intended for seed, three feet under the ground. We know that there are certain depths at which seeds will not germinate, and I believe Potatoes will not at three feet under the surface. To test this a few days ago, I mark a pit more than three feet deep, and put into it about 12 stone of Potatoes, and covered them with three feet of clay level with the rest of the ground, and have planted Cabbage over them. I propose planting Potatoes in the open field about Christmas, and in May I will open my pit, and plant one-half of the Potatoes that are in it; the remaining half I will leave till autumn, when I expect to take them out as good and as much as they are to-day. A difficulty in planting Potatoes in the autumn may be alleged in the former not having manure than for them; but this I hold is easily got over; the manure may be taken out of any time, and spread on the surface—the leaves of the plants will drive it in. Let large sets, from large Potatoes be planted, and the roots will want none of it. Hot dung, I believe, will come up even from [illegible].—*James, Mr. Goodlife, Gosport.* [Our readers must remember that this interesting communication relates to the mild climate of England.]

Propagation of Dendrobium, Pterodactylon, &c.—[illegible] Dendrobium and Pterodactylon during the [illegible] whether or not it destroys some insects, [illegible] time to [illegible]

Fly Hill.—[illegible] situation a [illegible] much [illegible] meal-bug; he has since succeeded in almost entirely extirpating these pests, by persevering in the use of the following mixture, and by (as long as was prudent) keeping the plants syringed with a weak solution of soft soap. The mixture was as follows:—2 lbs. of soft soap, 2 lbs. of flowers of sulphur, 1 lb. of roll tobacco, half a gill of oil of turpentine, and 2 oz of nux vomica (the latter in powder). The soft soap and sulphur should be mixed together with warm water, stirring them well together; the roll tobacco must be cut, untwisted, and boiled by itself for an hour and a half in a

saucepan, keeping the lid on, then strain it, and add the liquor to the sulphur and soft soap, next adding the nux vomica, and then the oil of turpentine. The whole when mixed together should make in all about five gallons. It should be applied with a painter's brush as soon as the leaves are off the Vines, and again just before the buds begin to break; after dressing the Vines with the above, some clay should be mixed with a portion of the mixture, to the consistency of good thick paint, and used for the purpose of stopping all cracks and holes about the Vines.—*W. Jones, Bulldinge, Surrey.*

Protection of Crops from Hares and Rabbits.—I would state, for the information of ——, that I, and one or two of my fellow-sufferers, did try and endeavour to keep down the trapping, shooting, &c., in a particular parish; although we thinned their numbers, to use a Yankee phrase, pretty considerably." Still I could see the old marks were not destroyed, for the next year the devastation was done, although not to the same disastrous extent as formerly. The case in point is as follows:—I had the ground trenched a very fine white turnip crop broke remarkably well, and for the first year would be sure to return undiminished; but this year was not to be a favourable one, for in the second winter of their trenching the enemy was at work, and most effectually did he do his work in many places the beautiful young shoots were browsed off, as though a whole herd of forest deer had been turned in; and, although many of the plants were from 5 to 6 feet in height the latter had been cut off 3 feet from the ground. To put a stop to such devastations, I adopted the following plan:—Having a decided objection to the smell of tar, I divided the whole piece of devastation with rope-yarn, fastening only all rubbish, such as Brambles, High Grass, &c., making a clear space for operating. I then had stumps fixed in the ground, at the distance of 12 feet apart, to which was affixed the yarn, in two lines, the lower one 6 inches from the ground, the upper about 16: there is no fear of either hares or rabbits jumping over (unless pursued), as they invariably crawl through or under any obstruction to their progress. To render the plan more effective, I occasionally applied the tar-brush, thereby causing a strong scent of tar constantly in the locality. By this plan I saved my crop, and now make it a standing rule never to have a copse unfurnished with the above preventive. I advised a neighbouring farmer to try the same plan with a piece of Carrots, and shut down in the very heart of the game preserves, and of which the rabbits particularly are so fond, as to deal with the like effect, assuring me at the time of fixing the drop, that he [illegible] rabbit [illegible] or top [illegible] to try this plan, feeling [illegible] at the same time [illegible] frequent applica- [illegible] tar [illegible]—*Thomas Gibbons, Bedlington, Durham.*

Sowing Seeds.—[illegible] seeds were steeped in a solution of [illegible] of ammonia, another portion in common water, and a third in a mixture of these, half and half. To [illegible] quantity of Pinks and Wallflowers were sown in the usual way. The seeds in solution of ammonia grew very quickly, and are now the largest plants of the [illegible] sowing. Those in nitrate did not vegetate, those in water languished, and those in the mixture flourished.—*W.*

Roses.—I beg to mention a mode of managing Standard Rose trees, different widely from the one formerly in vogue, and one which is very much admired here. I never prune or cut back the head of the tree, but merely thin out the very small wood, leaving all the strong and medium sized shoots to grow to their full extent. I have observed that in most varieties the medium-sized wood blooms the most freely, and treating in this way my trees are literally covered with flowers, resembling in their profusion and luxuriance the wild Dog Roses of the hedgerow. I do not understand this plan where Standard Roses are planted among beds of American plants, although, in my opinion, such is a most desirable situation for them; in such circumstances, however, the size of their heads would of course greatly depend on the nature and growth of the plants among which they were placed. When Standard Roses are planted singly on lawns or in avenues, nothing in my estimation can be more unsightly than the shapeless looking mop heads into which they are generally pruned, and which will not produce a fourteenth part of the bloom as when managed as above described. I remove the soil over the roots once in three years without disturbing the trees, and I replace the old soil by a little loam and manure, which I find very much invigorates the trees and renders them capable of bearing fine large heads, which almost conceal their naked stems.—*T. Shaw, Saltram, Crediton, Devonshire.*

Baskets rustic [illegible]—Some men are [illegible] with a peculiarly [illegible] skill, without [illegible] at the outset how it is [illegible] upon which their [illegible] depends. [illegible] is [illegible] from the [illegible] clearly upon what principle, in the [illegible] wicket-work, or, indeed, every [illegible] of any kind, are altogether out of place when surrounding flower-beds. I shall undertake, in reply, to give [illegible] rustic [illegible] and similar ornamental accompaniments are in perfect propriety—indeed demanded in such situations.—

The Late Frost.—The frost commenced with us on the night of the 5th, with some severity, as the annexed statements will show; our minimum appears higher than what is given as observed at Chiswick in the last *Chronicle*, 21° Fahr. being the lowest observed here on the night of the 6th; it may be as well to remark that the barometer has been high during the continuance of the frost, having during the greater part of the time been above 30 inches; and at 9 P.M. of the 7th it stood at 30·274; it began falling, however, on the 8th, and had its minimum on the 12th at 9 A.M., standing at 29·400. The wind during the whole of the [illegible] varied from [illegible] to E., and has [illegible] only [illegible] of [illegible] [illegible] Thermometer.

beautiful racemes of golden flowers, which continue until the end of November. It might be remarked, the clusters were not quite their usual length; but it was quite a novelty to behold such a display at that season of the year. I observed that in the flowering offsets produced on vegetation by extreme devotion to cuttings.—*W. M. Stubbs, Crowley Park, Oxfordshire.*

Pine Growing at Tyninghame.—In reply to Mr. Fulham's inquiries (p. 834), I beg to mention that I have tried the same practice as that of Mr. Dale for upwards of a period of eight years, but I imagine that I have during that time made some important improvements on the system, the results of which have been published in periodicals at different times. I would further state to Mr. F.'s information, that I believe the most essential points of my present practice of cultivating the Queen apple are entirely my own; and in order to satisfy Mr. F. of this fact, I beg to refer him to pp. 97, 98, and 99, of my Treatise on the Pine, where he will find a system mentioned differing very materially from any other that has ever been published. If Mr. F. has read my book, he will perceive that I have established a practice whereby succession plants and succession houses are superfluous; previous to this, such a practice was possibly not even thought of. To conclude, I may mention that I have so studied the real habits of the Pine, that I have rendered superfluous the routine of shaking out, potting, and repotting, &c.; and even where the pot system and fermenting materials are in use, such practices are unnecessary, except in the case of an accident occurring.—*Joseph Hamilton.*

Notes on American Plants.—I have read with interest the Notes on American Plants, by Mr. Reid, and I quite agree with him respecting Gerardia quercifolia, but not altogether as to G. flava; it being only a biennial, it would be a bad time to take up plants of it in June to send to this country. I have sent plants of it from Canada in autumn, but they did not succeed. I imagine that seeds are the only means by which plants of it can be obtained in this country. Regarding Asclepias tuberosa—amongst the many thousands I have seen of it, none were of a dazzling scarlet, but were from a pale to a bright orange; and with respect to A. quadrifolia, from Mr. Reid's description of it I imagine that he must allude to variegata. Convallaria racemosa (*Smilacina*, Pursh.), I do not consider a showy plant, certainly not so much so as Convallaria (*Polygonatum*, Pursh.), multiflora, or latifolia; the latter I have seen in Virginia, on rich ground, 6 feet in height. Houstonia cærulea I have known many years as a greenhouse perennial. It requires to be frequently parted, and should be planted in small pots in a sandy soil, and when kept near the glass should be placed on a shelf in front of the greenhouse, as it is not a very showy plant. Of Liatris, the species are certainly not all natives of the southern States; the following were found in Canada, viz., pilosa, scariosa, and squarrosa. There are many beautiful plants in North America that I have not seen in cultivation in this country; among these I may mention two, viz. Bartonia tricuspis and Botrichia canescens, which is found in Canada; and Puccoon, of the gardens, which is also a very handsome plant.—*B.*

Vegetable Instinct.—It has been to me a frequent subject of thought and observation, in the animal kingdom, where to draw the line of separation between instinct and reason. The instances are so numerous in which they seem to mix with each other, and become so blended together in the same individual, that it seems next to impossible to assign to each a distinct character from the other. In the whole organic world—the animal and vegetable kingdoms—beginning at man and gradually descending the scale through all its gradations to the zoophytes which connect the two, and from thence to the lowest forms of vegetable life, the Lichens and Algæ, we find in each the power of adapting circumstances by which they are surrounded, so as to contribute to their benefit in a greater or lesser degree. Now this power, when possessed by man, naturalists have defined as reason; in animals instinct, and in vegetables, *adaptation*. But I imagine that, in many instances, vegetables will be found to exhibit the property in a degree not inferior to many animals. It would appear that this power does not decrease with the scale of animal life, as many of the lower animals possess it in a much greater degree than some far above them in the scale of organization. The sloth and tortoise are familiar instances of the one, while the ant, the bee, and a host of subjects in the insect world, may be selected as illustrations of the other. In the vegetable world we have many instances, which, if not instinct, deserves a higher title than mere adaptation of parts to existing circumstances. Physiologists say that the cause of plants tending in partially illuminated situations, directing themselves to any aperture admitting light, is owing to the organ or cause of the stem most distant, being, by its action, contracted in consequence of the greater evaporation of fluids thereby, while the nearer is relaxed, or forcing the extremity of the plant in the direction of the light. This may be correct. But if a plant in a growing state is placed in a totally dark place, in such a situation contrary to its natural growth, the young branches will invariably be found to erect themselves. Again, by what influence, except that of mental support (they only adopt it in the absence of any other), should direct climbing plants to cling to each other till by their united strength they raise themselves in the air? Look at others which do not twine, but support themselves by bending the leaf-stalks around any object with which they may come in contact. The Mimosa pudyas offer an illustration of this. If a shoot of the plant be directed where there is no support, no bend in the leaf-stalk will take place, simply because it would be useless. But if after it has grown to a considerable distance in this way, a support be placed near it, the shoot directly will exhibit the hooked leaf-stalk, which in all its forms, vegetable instinct, or adaptation of parts, or what term soever it may be called, is equally applicable. A familiar instance among the common plants is the Pea, which, in addition to the use of its tendrils, possesses, in the leaf-stalk, a power of adaptation, which, when the tendrils are wanting, or are prickly, while the rose-tree, for example, is without them, it performs the office of both. Another

was planted in a large flower-pot, a growing specimen of a marked variety of Portugal laurel, called Oratorius, in East Lothian; and alongside of it a branch of the common Portugal Laurel, for comparison. This Caledonian variety is distinguished by being of more elegant habit of growth, having thick pellucid leaves, of a fine dark green colour on the upper side. Outside of these were arranged specimens of the variety of shipping used in the Peru trade, and of the Scotch fir, the produce of Dr. Neill, Secretary, both imported from Mrs. Gould Nab, the Curator of the Society's Garden, upon the principle of economical old pickle-pots, carefully tarred, and not to be seen in fashionable ware. The ground was by-the-bye introduced amidst the laurels, behind which the Deptford Ring (erected some time since in the Chapel Alley Building of Scottish heiths) was also encountered, and regarding which the Secretary read observations of Rumphorius, among which the Banda, were preferred, the climate of Scotland not having proved sufficiently good for the Wintera, nor for the Bletchingdon Raspberry, sent by Mr. Buist from Philadelphia. The Secretary also read communications from Messrs. Gordon and Forbes, of Gosmore Park, South Wales, on the Culture of the Pine-apple, and on Growing Cuttings in Sawdust, the latter of very large sizes from Mr. J. Middleton, the Management of the Orange tribe at Dunesgate, where fourteen kinds are cultivated for their fruit; and from Mr. Martin, Bhet Mill, on the Utility of the Sweepings of a Deer-shed in making up Cucumber [illegible]. Mr. M'Intosh, of Catherine-street, Edinburgh, presented a couple of his transparent waterproof linen, pulled as a substitute for glass, which after having been exposed to the most inclement influences for many months past, seemed with little very perfect condition. At this meeting the Hon. Lord Murray was chosen Vice-President, Professor Balfour, J. Edmond, Esq., W. Crawford, Esq., agent, Kennedy, Esq., of the Council, Mr. Neale and G. A. Eason, Esqrs., of the Garden Committee. All the other office-bearers were re-elected. Several new members were enrolled.

LINNEAN SOCIETY.

Dec. 17.—R. Brown, Esq., in the chair. A paper was read from Mr. Hogg, containing criticisms on a recent work by M. Lavrent, of Lyon, on the Hydræ and Sponges of fresh waters. This work, which had been presented to the Society by the Author, was one of the most complete on the subject, and was illustrated by numerous coloured engravings of the various species of animals on which it treated. Mr. Hogg stated that the author's work had not escaped criticism, observations which he had found on the locomotive power of the animalcules contained within a siliceous shell, and which were published in the Transactions of the Microscopical Society. Mr. Hogg also stated that the author had not noticed the remarkable fact, discovered by Dr. Grant, and published in the Transactions of the Linnean Society, that the sponges ought rather to be considered plants than animals.—Dr. Lankester exhibited a specimen of a fungus, apparently the Agaricus murinus, over the external membrane of the pileus of which, a second pileus, with its gills uppermost, was developed. The second pileus was immediately over the stipes, but seemed to arise from an extension of the growth of the gills, carrying on with it through the external membrane of the first pileus the internal or gill-producing membrane. A specimen of the flowers, fruit, and inner bark of the Cinchona Pitayensis, or Lac.-bark tree, brought from Jamaica by Mr. Wilson, was presented by Sir W. J. Hooker. The leaves of this plant almost always fall off in drying, except they are gathered when young. Mr. Robert Brown presented five species of Isoetes, from Algeria, two of which were terrestrial, and the whole had been collected by Bory de St. Vincent.

SOCIETY OF ARTS.

Dec. 11.—A paper was read on the Hydraulic Ram, by Mr. Row. A model and diagram accompanying the communication exhibited the machine consisting of a rectangular body, at the end of which is the supply pipe from a reservoir of water, elevated above the level of the machine, and from a running stream. At the top of the body, at one end, is a circular puppet-valve opening inwards, which allows the water to enter the body of the machine, but which closes when the water attempts to escape by the same way. At the bottom of the body, at the same end, is a circular valve opening outwards, which allows the water to escape, but which closes when the water attempts to enter by the same way. The other end of the body of the ram is fitted with a cylinder, in which a piston works, and which is connected with the air-vessel. The action is as follows:—The water entering the body of the ram with a certain velocity, acquires a momentum sufficient to overcome the pressure of the column of water in the air-vessel, and to force open the valve at the bottom of the body, and escape by the waste pipe. The momentum of the water in the supply-pipe being thus destroyed, the pressure of the column of water in the air-vessel causes the valve at the bottom of the body to close, and forces the water contained in the body of the ram through the valve at the top into the air-vessel. The momentum of the water in the supply-pipe being destroyed, the water descends in the supply-pipe, and enters the body of the ram through the valve at the bottom, and the same action is repeated. The water entering the air-vessel compresses the air contained in it, and the elasticity of the air causes the water to rise in the ascending pipe. The valve at the top of the body of the ram is loaded with a weight, which can be increased or diminished at pleasure, so as to adjust the pressure of the water in the air-vessel to the height to which it is required to be raised. The valve at the bottom is loaded with a weight, which can be increased or diminished at pleasure, so as to adjust the velocity of the water in the supply-pipe to the greatest velocity with which it can escape by the waste pipe

small sowing of the Early Frame Pea may be made; they will come in a little earlier than those sown in spring. Mushrooms, and all kinds of fruit trees, may now be introduced.

With regard to the former, which produce their fruit entirely on the previous year's wood, the old shoots should be cut out close after the gathering of the strongest of the young ones tied up in their place, and pinching clean off by the root all the rest of the young shoots. After they are tied up to the stakes, shorten them to 6 feet in height. In exposed situations, I prefer tying Raspberries in bundles to the points of the stakes, and shortening the canes to a foot respectively when they have done bearing, which gives a neat appearance. These Gardeners, who possess a frame, for training a few choice plants, should keep a sharp look out for insects; for in winter, when nothing else is growing, they cannot readily put fumigation in force, and if they do once get destroyed. Keep a sharp look out for the green aphis on Peaches, and give air every fine day, when not too cold.

State of the Weather at Chiswick during the last 10 years, for the ensuing week, ending Dec. 25, 1844.

Dec.	Average Temperature.			Prevailing Winds.								
	Highest Temp.	Lowest Temp.	Mean Temp.	No. of Years in which it Rained.	Greatest quantity of Rain.	N.	N.E.	E.	S.E.	S.	S.W.	W.	N.W.
Sun. 22	42.6	29.4	36.0	7	0.26 in.	1	0	0	1	1	2	1	1
Mon. 23	42.1	28.1	35.1	6	0.26	1	0	0	1	1	2	1	1
Tues. 24	42.1	29.1	35.6	6	0.26	1	0	0	1	1	2	1	1
Wed. 25	42.2	29.5	35.4	6	0.26	1	0	0	1	1	2	1	1
Thur. 26	42.3	29.7	36.0	6	0.26	1	0	0	1	1	2	1	1
Fri. 27	42.4	29.1	35.7	6	0.26	1	0	0	1	1	2	1	1
Sat. 28	42.2	29.2	35.7	6	0.26	1	0	0	1	1	2	1	1

The highest temperature during the past period occurred on the 26th, 1837—thermr. 59°; and the lowest on the 24th, 1840—thermr. 10°. The average temperature during that period is lower than that of any night throughout the year.

Notices to Correspondents.

Back Numbers of the Gardeners' Chronicle.—So many Back Numbers are now out of print, that we think it will save all parties trouble if we publish a list of those which may still be had. Any Subscriber who will forward to our publisher, Post-office stamps and wrapper, to the amount of as many Numbers as are required, shall have them sent free by post:—

1841.—1, 2, 6, 12, 13, 15, 16, 17, 18, 20, 22, 25, 26, 28, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52.

1842.—4, 6, 8, 11, 15, 20, 23, 24, 27, 28, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52.

1843.—2, 10, 11, 13, 14, 15, 16, 17, 18, 20, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52.

Address.—To the Exhibition Committee not having stated the depth of the pots in which these plants are to be grown, we have no authority for doing so. It is, however, obvious that the word is to be taken in its common acceptation; this will be sufficient rule for you. We apprehend that a specimen without much lateral branches than deep, and a pot on the contrary is much deeper than broad. A vessel which shall be of equal breadth and depth, or nearly so, is neither a pot nor a pan. As to the sorts of Achimenes, you will see that a great many names of nurserymen are so ill advised as to establish varieties of A. grandiflora, as species, they will be disqualified. The species of Achimenes are, 1, rosea; 2, Cocciniea; 3, pedunculata; 4, longiflora; 5, multiflora; 6, hirsuta; and 7, picta. All can be easily had except multiflora, which is not much in cultivation, and is not required to make up the number.

Bees.—*T. J.*—Newman's book is published by Andot, 8, Rue de Paon, Paris.——*R. Mc.*—There is no book on Entomology at the present time. The best articles we have are those which appear in this Journal. Every week, and you will know as much as is practically useful.

Calceolaria.—*Constant Reader.*—Kinghorne, Duchess of Sutherland, and Professor Wilson; Standish's Gracilina, Celebration, and Magnificent; Green's Zebra, Queen of Wales, Green's Prince Albert, Green's Adonis (improved), Albo coccinea, Green's Rainbow, and Green's Friend of Wales, and Standish's.

Cinerarias.—*C. J. R.*—Your plants are subject to the attacks of the Green Fly, which is the *Aphis Rosæ*. Fumigation, No. 2, and Kerria Victorina.

Cuttings.—*Novitiate.*—Gardeners have known the branches of such plants as Clematis, but not the leading shoots, when they are beginning to shoot.

Cement.—*A Constant Reader.*—Boiled linseed oil and litharge. It is a very old material in some respects, though new to others. Its business consists in the filling of the refrigerating it out of a joint into which it has been introduced, and that apparatus cannot be used again, it requires to be taken to pieces. Its use consists in its application as a cement. But the same substance is demanded as one that will unite red-lead and oil and turpentine, by some looked upon as burning.

Raising trees.—*A Subscriber.*—Trees in old pits will be underwood in plantations, and in perhaps, favourable situations, such as those in which the wild Hazel grows naturally, on steep banks facing the sun.—A loamy soil, not too deep, is proper for them. They require pruning; but the mode must be varied according to the soil and situation. Your trees, 2½ feet high, ought to bear the second year after removal.

Forest trees.—*J. Dee.*—Leave the shoots to handle-sized; there is little fear of their blowing off at the stool. When branches grafted on large arms of fruit trees are blown off, the decay of each an excrescent is quite unlike anything that can occur to strong shoots from the stumps of forest trees.

Fruit trees.—*W. D.*—The following will probably succeed in the north of Scotland, if you keep their roots near the surface:—Apples, dessert—Colin, Early Red Margaret, Pitmaston Nonpareil, Wormsley Pippin, Blenheim Pippin, Hacker's Pearmain, Court of Wick, Golden Pomeroy, Pitmaston Pine-apple, Bradwick's Nonpareil, Scarlet Nonpareil, Stunner Pippin. For kitchen use—Dumelow's Seedling, Tower of Glamis, Hawick Castle, Threecornered Beefing, Hollow Crown Pippin, Lord Suffield, Russet, Waltham Abbey Seedling, Yorkshire Greening, Keswick Codlin, Peters—Russet, Gratioli (or Spring), Winter Nelis, Kitchen of Comlongan, Marquis of Lorne, Easter Beurré, Winter Beurré, Glout Morceau, Colmar, Crassane.

Grapes.—The cause of your Vines not swelling their fruit is the want of sufficient heat. If they are so, no manure is to do the mischief your correspondent complains of. Mildew is caused by a want of air, and by keeping the house too close at the time of ripening.

Gathering fruit.—The objects of pulling fruit when green are these:—1. Generally speaking, fruit will ripen better on the tree than when gathered; 2, good appearance; 3, large specimens of glass covering sometimes keep fruit jones; 4, increased light to the specimens of late being avoided. It is obvious that the two last objects are best attained by having the fruit ripened on the tree; and we do not think that the first will be disputed. Upon the point of taste, however, we have at present no direct proof. If you have small squares of sheet glass you have more exercise in the gardeners' labour than if you have large ones. At Chiswick the squares are nearly a foot long in the great Conservatory." We should, however, think that for general purposes 18 inches are enough.

Greenhouses.—*Anon.*—The use of hollow walls in greenhouses is partly to keep them warm, and partly to keep them dry. They also should be rather cheaper than solid walls. They have no other advantage. When a room has had the dry-rot, nothing is gained by flooring it with Oak—for dry-rot fungi will attack one kind of wood as readily as another; and as for Oak, just think of what happens to ships. If you can get the timber thoroughly soaked in sulphate of iron, or corrosive sublimate, or chloride of zinc, any of those substances will protect it; but it must be thoroughly impregnated.

Heating.—*Z.*—If you take the lids of troughs off, in a *greenhouse*, in winter, you will kill or spoil all your plants. A *greenhouse* should be kept dry in winter. Give greenhouse plants a moist atmosphere when they are about to grow, and in full growth, and at no other time.——*A Beginner.*—By all means use iron troughs with moveable lids. Use one row only of such troughs. It is plenty. Certainly, glass frames for guarding the Vine border are much better than anything else; and you will not want pipes.

Indian Cabinet.—*E. M.*—If you will refer to p. 796 you will find an answer to your question.

Insects.—*Z.*—We never heard of such an insect as Tentania aurata, and imagine it must be a misprint. We hope some one acquainted with the species will be able to give us its correct name, and the family to which it belongs. *R.*——*H. R. S.*—Thanks for the worms: they are, we believe, the Gordius argillaceus. *R.*——*W. S. S.*—The dirty gummy exudation on your Rhododendron leaves may be caused by insects, but we can find none on the specimens sent. If you can detect any, and will inclose them in a pill-box, we will tell you their name. *R.*

Manure.—*T. D.*—The must or marc of a cider-mill is of very small value. Throw it to the dunghill; it will be of a little use there, and there only.

Mistletoe.—A correspondent reminds us that we did not name the Whitethorn as one of the trees which this plant affects. We beg to supply the omission now. There is nothing which the Mistletoe prefers to Whitethorn, Apples, and Crabs.

Names of Fruits.—*C. H. W.*—1, Dumelow's Seedling; 2, Court of Wick; 3, 9, Rymer; 4, Dumelow's Seedling; 5, King of the Pippins; 7, Dutch Mignonne; 8, Beauty of Kent; 10, Fearn's Pippin; 11, Uvedale's St. Germain.‖——*A Constant Reader.*—1, Keswick Codlin; 2, Hollow-crowned Pippin; 4, Kentish Fill-basket; 5, London Pippin; 6, Pomme de Neige; 7, Crimson Queening; 8, Lucombe's Seedling; 9, Northern Greening; 10, Margil; 11, Stagg's Nonpareil; 12, Ross Nonpareil; 14, Syke House Russet; 15, Pearson's Plate.‖——*J. F.*—1, Blenheim Pippin; 2, Rhode Island Greening; 4, Glout Morceau; 2, Colmar; 4, Crassane.‖——*C. W. K.*—1, 8, 10, Pomme de Neige; 2, Ribston Pippin; 3, King of the Pippins; 4, Blenheim Pippin; 5, Gravenstein; 6, Braddick's Nonpareil; 9, Margil; 11, Scarlet Nonpareil; 12, Easter Pippin.‖——*J. M., Cheshire.*—1, Stagg's Nonpareil.‖——*W. G. H.*—Your Apple is the Newtown Pippin, and a fair specimen for this climate.‖——*M.*—Your Apple is the Turk's Cap.‖

Names of Plants.—*Constantine.*—1, Polypodium vulgare; 2, Ceterach officinarum; 3, Rumex sanguineus.§——*A. M.*—Ophiopogon spicatus; if you wish for correct names you should send good specimens. How is anybody to judge correctly of such a morsel as you sent before?——*G. W. H.*—Some species of Trichosanthes, a poisonous gourd; the species not determinable from such a bit as you have sent. The Fox Grape is Vitis vulpina, and derives its name from the foxiness of its ripe berries; some persons like the taste, we think it particularly disagreeable.——*S. W.*—Apparently the smooth variety of Rosa Carolina; certainly not *R. lucida.*——*N. Mitchell.*—Ceanothus azureus.——*A Constant Reader.*—The double dwarf Almond (Prunus japonica).——*K. C.*—Pitcairnia flammea, not staminea.——*B.*—Oncidium sanguineum.——*C. W. K.*—Eulophia macrostachya.

Natural Classifications.—*A Student.*—We have your paper in type: but neither we nor our printers can decipher some parts of it. Will you give us your address, and read the proof yourself?

Peas.—*W. Bartlett.*—The guide and stake boxes, 2½ feet by 2½ feet high, in an excellent situation for Peas. If the soil is good the roots will thrive very well beneath the paving bricks. Marie Louise and Gilott Morfeuil are the dwarfest varieties of plants.

Pelargoniums.—*J. M.*—Matilda, Lord Lyons, Sir R. Peel, Erectum, Pulchellum, and Duke of Cornwall.

Rainwater.—*A. E.*—Put cold spring pipes into the middle of the tank, and the evil of contaminating the water, and the greater the water the more the mischief. We should have said the same pipes, but under your circumstances, you could not have them in almost any other manner.

Roses.—*J. C.*—Under all the circumstances of your Tea Roses under a north wall, without protection, you may reckon upon losing many of them in winter. Instead of putting them in pots, you should have them planted out in a border, and if you protect them with a little litter in winter, they will do well. Choose the warmest and most sheltered place you can find. You are well advised not to prune them in autumn. Wait till spring, and then prune them moderately well. Do not prune now, but some time in February. Your Roses will be much benefited by the change.

Soil.—*Y. Y.*—Put down no soil upon your roots, but let them be perfectly well drained. Pack them in, when by keeping them close and cool they will be sufficiently established to bear a little exposure to the air, by degrees.

Stable.—*W.*—We think your stable will be warm enough, if properly constructed. The horses, because of the ammoniacal gases, will require to be kept clean. The cooling will then be of the same temperature as the stable. In the stable itself, the ammonia from the urine of the horses will be sufficiently counteracted by the ventilation. And here we have a question which we have long wished to put to Mr. Loudon, and his answer in this:—Why do not gardeners use the ammoniacal gases, to nourish crops upon the ground? Whether it be a fact or merely the thought of the moment, we have not yet seen it stated. Then, will produce a more equal temperature in the apartment. Some of what Gardeners, when the gases themselves upon the ceiling, when they are plastered. A stable or a chamber, which is immediately under a roof, will always be cold in winter, and hot in summer. The ventilation of a stable is best effected by a wooden flue, six or eight inches square over the head of each horse, rising above the roof, and terminating in a cowl, or in a cap, so as to prevent the possibility of down-current. To prove this, there must be more than sufficient ventilation to carry off the gases. Stables are generally too small, and such a place is much more easily found in a large than in a small stable. The comfort of the horse is much promoted by a loose box, with a comparatively small descent from head to heel, but with a considerable descent from side to side. Above all, let the floor of the stable be no lower than the surrounding earth, especially in damp situations.

The Rose Garden.—*A Subscriber.*—We have received from a gentleman who claims the authorship of this production, noticed at p. 815, a request for explaining the manner in which it was criticised. We had no idea that so estimable a naturalist as Mr. —— was concerned in writing it, and we have too much regard for his reputation to make matters worse by publishing his letter. Upon looking to the work in question we must say that we agree with the writer of the critique in the opinion that the execution of the correspondent exhibits little for the encouragement of the information it contains, by being limited to a certain number of roses," and he denies the truth of the whole compilation that the nomenclature of Rivers is "that followed by botanists in general." Mr. —— is not a botanist, and the instances to which the names belong in the first excuse is inadmissible; and with regard to the second, we think that all who write English Gardens will find the following synonymes useful. Arbuscula, Banksiæ, Tydeiæ, Chinensis, and Agrestis. They do not appear in the works of Curtis or Stephens, and have never come under our own observation.

Transplanting Mangel-wurzel.—*Ibid.*—The Cuscuta epithymum, or Lesser Dodder, is not in any way different from the common Thorn, except in its habit being more prostrate. There is no other species which attacks Furze.

Tarring nursery.—*Gower Gardening correspondent*, under date, Cork, Dec. 13, will see by our statement, last week, that the information had been previously published. Everybody is liable to such things; and no person knows the readers of Newspapers. There is no harm done after all.

Verbenas.—*J. I. R.*—Youell's Princess Royal, White; Gibbs's Boule de Feu, Scarlet; Beauty Perfection, Lilac; Mellendres Superior, purple; Cerise, Nil plus Ultra, rose; Ivery's purpurea perfecta, f.

Vines.—*A Subscriber, Chiswick.*—For a Peach house, and as a succession, Black Hamburgh, Royal Muscadine, Black Prince. The Victoria Vine is considered the same as the Black Hamburgh.——*Walter.*—The White Muscat of Alexandria has not been distinguished in point of flavour by any new introduction yet known. You may therefore plant one of it in your hothouse. White and Black Portugueze; Black Prince; Black Hamburgh; Black St. Peter's.——*W. G.*—Black Muscat of Alexandria, Black Damascus, White Nice, and Grizzly Frontignan, or, as these three ripen about the same time, if you omit the White, according to the dimensions of your house, you must plant another Vine to make up the number. Add to this one or two Sweetwaters previously determined on, &c. &c.

Vine-borders.—*M. C. D.*—Bodies buried in the earth do not putrefy, but they assist in feeding the plants and preventing the ground from becoming sour. Your borders are good as they are, and if they have a proper degree of moisture and slope, they are special as a means of retaining moisture in dry weather. Be sure to keep your border dry in winter, and do not allow the water from the roofs to run upon it. Your Vines will do well.

Weeds in Manure.—*A. W.*—The best way of destroying the seeds of weeds in manure is to put the latter in the tank, as you have done, with lime between each layer, as well as dung for fermentation, and consequently heat, and germination of the seeds; for in the absence of light the vegetation of these proceeds a certain stage and stops.

Miscellaneous.—*Lucius A.*—Your Grapes appear to be suffering from want of warmth, and perhaps, also, from the soil not being rich enough. Perhaps, too, they are overwatered at the roots. At present, we should think, and very strongly, that your Vines have been injured by the cold, but we cannot say whether this has been a little summer, but bringing, would not have prevented that. *A Subscriber, Dundalk.*—Hand over your seeds to Mr. Ivery, Covent Garden, and he will sow them in his cabin. If you cannot do that, put the bag in a desk box and insure its being kept in a cabin. If it is sent below, the seeds will be the worse for the voyage.——*Inquirer.*—Conveyances in parts of Cheshire, Bedfordshire, Hants, and all parts of what are called *inland counties*, are the most suitable for Jamaica.——*A Subscriber.*—A dilapidated soil for Pears is good, rather stiff. Would the surface of an old pasture, broken, and mixed with manure, which should be well mixed with the soil. Cucumbers will succeed in soil composed of turfy matter, like that under the surface soil of the pasture named, one-third well decayed manure, and about the same quantity of rotten dung. Collect leaves now, and lay them with a heap in the compost ground to rot. Your soil appears to be excellent for Vines. Give the mould from the bottom of the hole of your Vine-border, which are quite wide enough. Your plan of watering is good. Mr. —— is perfectly right in his way of watering. It is the consequence whether you pull the stake up with them or cut them down by the roots. Your Vines are evidently weak; but you have not stated the kind.——*A Constant Reader.*—Apply to the Secretary of the Horticultural Society, Regent's Park.——*Inquirer.*—Apply for the Orchideæ to Loddiges, Hackney.——*W. Coe.*—Use a camel-hair pencil, and with it brush the pollen out of the anthers, and apply it to the stigma.——*Ivy.*—Ivy is your natural aspirations.——*Gem.*—We prefer the first to the second.——*Constant Reader.*—Your letter does not contain sufficient evidence of the case to enable us to form an opinion. Your plan of watering your Vines is much better than that of syringing. Put a mat or two over the border, and let the rain run off. Your Vines are evidently weak; but you have not stated the kind

FARM WANTED, to contain from 50 to 100 Acres or thereabouts, of good land, well drained, with or without a residence. If within 10 miles of London and near a railroad station it would be preferred. Particulars to be addressed to A. B., Mr. Wood's, Old Bond Street.

The Agricultural Gazette.

SATURDAY, DECEMBER

[illegible]

[illegible] in what long practice has shown to be the surest and most effectual [illegible]

We do not wish here to draw any [illegible] between the vegetable and animal kingdoms, and [illegible] from it this great improvement in agricultural *plants* will [illegible] the probability of this we have already shown, but we may [illegible] that the same activity and energy to which the above valuable results are due, and which have doubtless been the means of [illegible] in breeds of animals, by the annual award of valuable premiums for the best animals of [illegible] may similarly be excited and maintained among those whose attention is directed to the improvements of vegetables. The comparative neglect with which the claims of *them* to the patronage of our national Agricultural Societies have been treated, cannot certainly be defended on the score of any alleged insignificance of the subject. Why, it is held to be axiomatic, that of the two branches of farming—the *production* of food, and its *conversion* into beef, mutton, &c.—the former is the *more important*;—that cultivation proper, to which we owe grain and other esculenta, food for man—as well as roots and forage, food for beasts—is greatly more important than that branch of farming which takes account merely of the breeding and feeding of live stock. One reason of the neglect to which we allude probably lies in the difficulty of fairly estimating the value of vegetable specimens; they depend so very much on their treatment, independently of any *specific* distinctions which they may possess, which alone, it is to be observed, should be the subject of reward. To this question we shall return at some future period; in the mean time, we take the opportunity of laying before our readers the following communication, from the late Sir F. A. Mackenzie, in the spirit of which we entirely agree: it was published in an early Number of the *Gardeners' Chronicle*, for 1842:—

"I am gratified to find that you advocate a cause which I have earnestly espoused for several years, though with but little success. I allude to the paying more attention by our English and Scotch national Agricultural Societies to that subject which is the foundation of all agricultural wealth—grain and roots—or, as many would term it, vegetable produce. I had the honour—no pleasure, as it has turned out a fruitless duty—to be named president of the root and seed committees for the Highland Society, in 1839-40; and in our report of 1839 I specially alluded to the absurdity of allowing so trifling a sum—only five pounds I think—for the discovery of new and superior kinds of grain or roots, whilst hundreds of pounds were voted as premiums for animals whose very existence and superiority depended entirely on the quality and quantity of the neglected roots and grain. Little attention was, however, paid to that report, and I determined that if again named president of that committee—which I was—that I would propose some names of authority to act with me, who might have more weight with our Society's committee of management than I found allowed to my own opinions. Accordingly, I got the names of my two friends, Col. Le Couteur and W. Gibbs, added to our committee, and they both very kindly attended our Aberdeen meeting, and cordially agreed with me in drawing up our report, which expressed more strongly than that of the former year our opinion of the absurdity of giving 20*l.* or 30*l.* as premium to one bull or other animal, whose blood and good qualities could not be spread over any great extent of country, whilst a more perfect or earlier kind of Wheat, Barley, or other grain, or a superior Turnip, Potato, or Carrot, was almost totally neglected; though, were its merits made known by a handsome premium, it would be introduced in a short time over the whole country, benefiting thousands of our agriculturists, and through them the nation. Can such be said of prize bulls, rams, boars, or stallions, except after the lapse of a great many years? And what has been the result of our report to the Highland Society? That a better premium was offered for a short-horned bull—100 guineas—than had ever been given before, whilst the despicable seeds and roots were left to their former paltry condition, and the premium cattle, as Le Couteur and others said to the wind, because they had not the good fortune to be approved of by committees. And, sir, who knew better than the sub-committee what were most valuable to the country, will not have the kindness to answer me? I say do not let the stupid cry as some Societies do, who shall be nameless, of the fashionable fashion of setting a high value on animals alone, would subside and the committees of the whole of our Societies, but the public attention attracted to their care would be directed to these neglected really of greater value, when I can assure you our vegetable kingdom. It is my intention this year to propose that both our Royal and Highland Societies shall devote at least as large a sum yearly in future to the discoveries of early Wheats and other improved kinds of grain, to superior Turnips, Potatoes, and other roots, as to animals; and I hope to the support of every well-wisher to our rich and prosperous [illegible]

AGRICULTURAL EXPERIMENT.

[illegible] the cultivation of artificial manures, that even the [illegible] which is now [illegible] has failed to benefit [illegible] according to the testimony of an intelligent [illegible] neighbourhood, who had tried it [illegible] several preceding seasons. I was deterred from prosecuting my experiments with them on a large scale, not only from the fear of loss to myself, but still more because it would not be a fair test of their value. But there are other questions interesting to the farmer the conduction of which does not depend upon the season. Two of these are, Which is the best mode of putting the seed into the ground, whether by drilling it or dibbling it, or sowing it broadcast? and if drilling be adopted as the best, which is the best interval between the rows? Perhaps it will be said that this is to call in question the most elementary principles of Agriculture; that the superiority of the drill over the broadcast system has been demonstrated long ago, and is acknowledged in practice wherever the cultivation of the soil is best understood. This was my own conviction, and it was principally with a view to convince those who still adhered to the contrary opinion, that I determined to give both systems a fair trial. Accordingly, in a field which was very evenly covered with an excellent crop, 4 perches of each were taken for the comparison, and the produce measured and weighed. I subjoin the results:—

	Straw per acre. trusses, lbs	Corn per acre. bshl. gals.	Weight of Bush. lbs.
Drilled Wheat	95 20	40	60
Broadcast do.	97 20	35	61

The spaces thus measured seemed, as far as the eye could discern, to be perfectly fair samples of the respective crops; but for the sake of greater accuracy two whole lands were taken for comparison; when these, however, were afterwards measured, they were found to be unequal; and I mention this, because the upper portion of the field having been more highly manured than the rest, over a space contained within parallel lines, that inequality gives an advantage to the broader land in the computation of the average. The produce was as follows:—

	Straw per acre. trus lbs	Corn per acre. bshls. gals.	Weight per bushel lbs.
Drilled Wheat [illegible]	90 12	34 1	62
[illegible]	91 12	33 6	
Drilled Wheat [illegible]	88 20	36 7	62
[illegible]	92 8	32 6	61
[illegible]	97 8	30 —	62
[illegible]	105 32	42 4	62

In the first of these instances a second stirring of the ground appeared to be beneficial; in the second the want

So, then, the less the ground was stirred the greater was the quantity of corn which it produced; a conclusion so contrary to reason and experience, that it can only be considered as an exception to ordinary rules, and referred to some unexplained cause; and it is [illegible] to be observed that the increased quantity of the broadcast corn was obtained at the expense of its quality. In the [illegible] field Wheat was [illegible], but it never came up, and the ground was ploughed up in the spring and [illegible] but it was too late, and the produce was only 25 bushels per acre. The grain was probably [illegible] by the dibbles; for the soil [illegible] the chalk constitutes [illegible] a most adhesive plaster, through which the [illegible] with difficulty percolates. [illegible] another experiment in another field [illegible] dibbled against broadcast Wheat; the best of two portions of the former selected for comparison yielding 6 bushels per acre less than the latter. In the other experiments which I have to mention, the results were [illegible] in accordance with the theory of good cultivation.

	Straw per acre. trus lbs	Corn per acre. bshls. gals.	Weight per bushel lbs.
[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]

How the quality of the corn is in favour of the drilled, but the quantity of straw is in favour of the broadcast; more, however, was sown in the latter case than in the former, 10 pecks instead of 9. It will be observed that the measurement on a large scale requires the calculation of the average by [illegible], but perhaps this is to be attributed to some variation in the soil; for ten other experiments in the same field, comprising altogether more than a quarter of an acre, which is generally considered sufficient for ensuring an average average of more than 38 bushels per acre, and when the field was sown, the drill was employed on three-fourths of the remainder, which on that account was [illegible] sown by hand. The results of the next experiment were still more paradoxical, and contradict one of the common maxims of good husbandry. It was tried on a field of very inferior quality, the situation being high, and the soil shallow: the quantity measured in each case, was 6 perches.

	Straw per acre. trus. lbs	Corn per acre. bshls. gals.	Weight per bushel lbs.
Wheat drilled and harrowed	66 —	25 —	62
" drilled and [illegible]	39 —	22 —	62
" drilled and handhoed	40 —	23 —	62
" drilled and [illegible]	[illegible]	23 —	62
" [illegible]	60 —	25 —	62

So, then, the less the ground was stirred the greater was the quantity of corn which it produced; a conclusion so contrary to reason and experience, that it can only be considered as an exception to ordinary rules, and referred to some unexplained cause; and it is [illegible] to be observed that the increased quantity of the broadcast corn was obtained at the expense of its quality. In the [illegible] field Wheat was [illegible], but it never came up, and the ground was ploughed up in the spring and [illegible] but it was too late, and the produce was only 25 bushels per acre. The grain was probably [illegible] by the dibbles; for the soil [illegible] the chalk constitutes [illegible] a most adhesive plaster, through which the [illegible] with difficulty percolates. [illegible] another experiment in another field [illegible] dibbled against broadcast Wheat; the best of two portions of the former selected for comparison yielding 6 bushels per acre less than the latter. In the other experiments which I have to mention, the results were in accordance with the theory of good cultivation.

	Straw per acre. trus lbs	Corn per acre. bshls. gals.	Weight per bushel lbs.
[illegible]	[illegible]	[illegible]	[illegible]
[illegible]	[illegible]	[illegible]	[illegible]
Drilled Wheat [illegible]	90 12	34 1	62
[illegible]	91 12	33 6	
Drilled Wheat handhoed	88 20	36 7	62
[illegible]	92 8	32 6	61
[illegible]	97 8	30 —	62

In the first of these instances a second stirring of the ground appeared to be beneficial; in the second the want

[illegible] [illegible] [illegible] [

of it administered both the value and amount of the produce; for hand-hoeing is such an inefficient operation, except for the extirpation of weeds, that little advantage could be expected from it. Intimately connected with these trials is the further inquiry, with what intervals Wheat should be drilled?

	Straw.	Corn.	Weight.
At 6 in. apart 4 perches gave	32	157 4	62
At 9 " "	19½	64 4	61

Here the excess of quantity seems to have injured the quality; but in another field the same effect was produced by a different cause. Four intervals were tried, the produce was—

	Straw. per square yard.	Corn. per square yard.	Weight.
At 6 in. hoed twice but not rolled	28	146	62
At 7 in. hoed twice, rolled with 4 horses	27	146	62
At 8 in. hoed twice, rolled with 2 horses	28	146	62
At 9 in. hoed twice, rolled with 2 horses	28	146	62

The portion of ground on which these experiments were tried was taken for that purpose out of its natural course, having borne a crop of Wheat the year before last; in order, therefore, to bring it back into the usual series of crops, it was sown with Clover, which in the three closer intervals failed entirely, that in that of 9 inches was strong and covered the ground. Now, since where two crops grew together the second must rob the other of part of its nourishment, the inferiority in the latter case is no more than might be expected.

Another point which I wished to investigate was the practicability of supplying the defect of substance in grain by the addition of ailment to the growing plant, and so making the worst seed answer the same purpose as the best. Some bad Barley having come up sufficiently well, was manured with phosphate of potash, at the rate of 1 cwt. per acre.

	Straw. trusses. lbs.	Corn. Weight. lbs. gals. lbs.
6 perches of it gave	37 90	90 5 48
Good Barley without the phosphate	35 20	87 4 50

The seed being so very thin, the land that scattered it would hold many more grains, and this will account for the greater bulk of straw; notwithstanding which the corn was inferior both in quality and quantity, but not so much as might have been expected; and, perhaps, if some sulphate of ammonia had been added, the result might have been very different for where it was applied to that part of the field where good Barley was sown, the produce was increased by almost 7 bushels of corn per acre, and more than 7 trusses of straw. The remaining experiments having been made in garden ground, and consequently on a small scale, it will be sufficient in the end of calculating the average of each to give the weights actually weighed, and the quantities actually measured for the purpose of comparing the result to one another; this will be more accurate.

Two adjoining plots of ground being sown, one with tailing Wheat, unsaleable otherwise, with good Wheat, in the spring both were thickened into 4 parallelograms, and one in each row, containing a space of 36 square yards, was left without any manure except that the whole ground about two inches deep was covered in April with a solution of 2cwt. superphosphate of potash; the third par. with 1 lb. of the phosphate, and 1 lb. of sulphate of ammonia; and the fourth par. with 2 lbs. of sulphate of ammonia. All these contained 35 square yards. The produce was—

Tailing Wheat, worst that could be selected.	Weight of Straw.	Weight of Straw.	Quantity of Corn.
	lbs. oz.	lbs. oz.	gall. qr. pt.
1 Unmanured	11 8	19 8	1 2 0
2 Phosp. potash	18 0	25 8	2 0 1
3 Phosp. potash	15 9	27 4	2 1 0½
4 Sulph. ammonia	14 12	30 14	2 2 1
GOOD WHEAT.			
1 Unmanured	20 12	24 6	1 3 0
2 Phosp. potash	22 6	32 6	2 1 0
3 Phosp. potash	19 12	34 12	2 2 0
4 Sulph. ammon.	18 4	30 1	2 2 0½

It appears, then, that although the worst seeds are certainly less productive than the best, yet the difference is not so great as might be expected; and that upon soil which is capable of producing a crop, about to bolt ripe here, when the plant is fed by an excess of ammonia, there is no difference at all, at least none worth consideration. The value of this manure is again satisfactorily displayed, the crop being increased by it at the rate of about 50 per cent. I had expected more from the sulphate, but that turned out to be not a fair trial. It is impossible to guard against all sources of inaccuracy; and in this case, some rats had burrowed under those portions which were so manured; and when the corn was ripening 5 children were killed. The cunning creatures had gnawed the roots of several plants in order to bring them down, and then gnawed off the ears, and carried them to their nests. The quantity thus destroyed was considerable; but supposing both to have suffered in equal proportion, I must infer that the other manures cannot compensate for the inferiority of the bad seed, though it is doubtless by them to produce a great deal more than the good seed left without their assistance.—*L. Vernon Harcourt, West Dean House.*

(To be continued.)

GYPSUM AS MANURE.

Gypsum was not used in agriculture till the latter half of the last century. First, it met with much antagonism; now, however, it is considered everywhere as one of the most superior manures, and if we do not find it acting with equal power in all localities, we may say, that this is not to be ascribed to the gypsum, but to other causes not yet explained. It is true, of gypsum especially, as of many mineral substances generally, that small quantities only are required for improving vegetation, and if it be thought that this be caused by some sort of stimulus which it exercises over the plants, this is not the case, because it has been found by many experiments, that the plants really do feed on it. If it were merely a stimulus, it ought to be contended that it will improve the growth of all crops, but we see on the contrary, that it affects more chiefly which contain much albumen, gluten, and legumen, which is said to be supplied by the food for substances requiring sulphur for their chemical composition, which is imparted to the plants by the sulphuric acid of the gypsum. That it is really the sulphuric acid which is useful to the plants, we may learn from other sulphuric salts (for instance, sulphate of iron), when employed in small quantities, acting very beneficially on vegetation, as well as from the fact that gypsum will be useful even on calcareous soils.

There are several sorts of gypsum which may be used as manures: there is one of a crystalline granular character (alabaster); others fibrous, scaly, earthy, &c.; there is also one which contains no water, and therefore consists of 58 parts of sulphuric acid and 42 parts of lime. The earthy is mostly mixed with particles of marl, whilst the scaly contains an admixture of a little oxide of iron, bitumen, common salt, &c. The extraneous admixtures at times increase its value as a manure, at others they impair it, which is to be attended to in its selection and use.

Before gypsum is used it is mostly burnt, because it will be then easier converted into a fine powder. By the burning it loses nothing but the water of crystallisation, or the chemically bound water (21 per cent.). If burnt gypsum be left lying in the air, it will again attract from it as much water as it had previously lost, which becomes again chemically fixed. It is soluble in water: still, 450 lbs. of water will be required to dissolve 1 lb. of gypsum. The property of being pretty easily soluble in water, and so sinking with it in the subsoil, explains why the manure with gypsum is so often to be repeated; because, if at one time only 80 lbs. be used per acre, they ought to suffice longer than we find to be the case, as one crop will not absorb more than 7 or 8 lbs. of gypsum. It does not cause any decomposition in the soil, nor is it changed itself, except if the soil contains much free humic acid, or if it be strewed (as is now often done) over the fresh dung and ploughed in with it, in which case it will sustain a partial decomposition by the carbonate of ammonia, developed from the excrements, so much so, that sulphate of ammonia and carbonate of lime are formed; generally, therefore, it passes (solved in water) in an entire state into the plants. It is generally strewed over the growing young crops, and farmers like it well, if they are yet wet from dew, as it is believed that it will then act as a better stimulus upon the leaves. Still, experience has shown that it will produce the same effect if it is washed off the leaves by rain-water; nay, it has been found that it will, in most cases, improve the growth of Clover (which is mostly manured with it) best, if it be strewed over the field before winter, and harrowed in with the seed. This phenomenon is easily explained by the gypsum finding the sooner in the soil the water required for its solution; and it being now distributed over the whole furrow-slice, it can be easier received by the roots of the plants.

Generally, double the quantity of the Rye used for seed, is employed of gypsum, but there are also soils where only 33 lbs. per acre must be used at once, lest it should over-force Beans or Peas. On some soils gypsum will not act at all, which will be the case if they possess already a sufficient quantity of it. It will be most useful to light soils, as they lose the soonest by the rain-water that gypsum which has been conveyed to them by the dung; whilst clayey soils will retain it longer. At times, gypsum will not produce any effect, on account of the soil being deficient in one or more substances required for the growth of plants; for that such a simple substance as gypsum may act beneficially, the soil must possess all the other substances required for vegetation. There are many places where gypsum once greatly improved the growth of Clover, whilst its application is now without any result. The cause might be, that the soil below the furrow-slice, in which Clover reaches with its roots, does not possess enough of potash, phosphate of lime, &c. Because it is plain, like the Clover, requires these substances for its growth, and if only one is deficient, it is clear that the remaining fourteen will avail it nothing, even if they were abundant. It is not, therefore, that gypsum will produce the best effect on such soils where, chiefly before, that land has been used as the soil will draw received by the subsoil, but on account of its advantages, but on gypsum. The addition of gypsum will thus cause the subsoil to obtain by no other permanent improvement, and it depends yet on other circumstances of which I shall mention the most important. It will not beneficially act on wet, marshy years, as in this case the water will not only convey it to the plants, but also will favour the assimilation of sulphuric acid; the leaves will only decompose the sulphuric acid by the influence of the solar rays, whereby they exhale the oxygen and retain the sulphur for the formation of albumen, gluten, &c. That this process really takes place in leaves is to be seen by the gypsum acting very little in wet, dank weather, and that, being strewed over Clover growing in the shade it will avail it nothing at all. If manuring with gypsum is to be useful, the soil must always contain humus, even if it be only 2 or 3 per cent., as the humic acid has also to transfer other similar substances to the roots required for vegetation. If, however, it contains too much of free humic acid, it will decompose the gypsum, so much so, that humate of lime will be formed and the sulphuric acid will be set free, which may then act as a corrosive on the roots of the crop. On that account, soil very rich in humus must never be manured with too much gypsum, because though the sulphuric acid were to combine with another base, contained in the soil, it would still form therewith a salt easily soluble in water, by which the plants will receive too much sulphuric acid at once.—*From the German of Professor Sprengel.*

SKETCHES OF EAST LOTHIAN HUSBANDRY.

Farm Servants.—In the following cursory remarks on the management and condition of the farm-servants in this county, I shall advert—1st, To the manner of hiring, 2d, To the amount of wages and mode of payment; and 3d, To their general character and condition. By far the greater part of the regular farm-labour is performed by married servants, usually called hinds. They are hired annually from the 26th May (Whitsunday, O.S.), to the same period of the following year; but there are numerous instances of servants remaining with one master throughout the currency of a lease. Indeed, comparatively few leave their places at the expiration of a single year. When a farmer is desirous of retaining any of his hinds in his service for another year after that which he is then serving, he must inform each of those whom he intends to keep of his wishes at a certain time before the Whitsunday on which their term expires. This day, which is called "speaking time," occurs in the beginning of February, and is general throughout the county. The servants to whom their masters do not "speak" at this period, infer that their services are no longer required, and look out immediately for other employers. Regular hiring-markets are held at Haddington and Dunbar, at which hinds are engaged for the year subsequent to the approaching Whitsunday. Certificates of "industry, sobriety, and fidelity," are generally required from servants before engaging them. The employer has to remove the hind's furniture, &c., from his former to his new abode. Single servants, boarded and lodged in the farmer's house, are hired by the half-year. The hinds are always paid in kind, or with the produce of the farm. The following are the quantities of grain, &c., which they receive, and the prices of each article computed according to its market value in February last:—

9 qrs. of Oats, per [illegible] value	29 10 0
2 do., 2 bushels of Barley	3 10 0
2 do., 2 do. of Beans	3 10 0
Cow's grass	5 0 0
In lieu of [illegible]	0 0 0
Potatoes, two yards long, a drill	2 0 0
Twenty-four [illegible]	2 0 0
Twenty-four [illegible]	0 0 0
Twenty-four [illegible]	0 0 0
Twenty-four [illegible]	0

whole of their wages in the necessaries of life; they have thus all the necessary articles of food continually at hand, and the quantity of corn and butter which those with moderate families are enabled to sell, provides for other demands. It is evident that the actual money value of a hind's wages cannot be accurately stated, as this must depend on the market prices of the articles in which he is paid; but it may be observed, that the seasons which are the worst for other labourers are usually the most favourable for hinds, because the additional corn, of which they can dispose, returns a better price. The numerous advantages arising to farmers and labourers from the general adoption of this mode of payment are clearly set forth in the following extract from Sinclair's "General View," &c.:—"Wherever labourers are paid in money, if they have the smallest inclination to be extravagant, they are furnished with the means. Having money among their hands, they do not scruple to gratify the present propensity, and live in expectation that pay-day will soon return. They are even laid under temptations to dissipation, though they may have no natural inclination to it; they must often, in procuring necessaries for themselves and their families, have occasion to meet their neighbours, with a little time to spare and a little money in their pockets: they must have a little conversation, that can be enjoyed to greatest advantage in the alehouse; and why may they not enjoy themselves with a little of the money for which they have toiled so hard? Thus love of society at first, and afterwards love of liquor, induces a habit which the prospect of distress and infamy cannot counteract, and which had probably never existed if the unfortunate beings had been paid for their work in the necessaries of life, instead of being subjected to the hazard with money to procure them. The cottage system, which found many advocates some time ago, was far inferior in every view of the matter, to the manner in which labourers in agriculture are accommodated here. Many of those who laboured to introduce the new cottage system, deserved all praise for the purity of their motives; every friend of humanity will honour them for the generous interest which they felt in behalf of the labouring poor; but if they had understood the condition of the hinds in this county, they would have found out a much better plan for accomplishing their object, than giving to every cottager land to produce his subsistence. A hind here receives as much corn as such a cottager might be expected to raise; his work for his employer is not interrupted, nor himself worn out by extra and excessive labour; he has no care upon his mind, no rent to pay, no bad seasons to dread; for whatever may be his master's crop, he is sure of his full share. If the labourer profit by this system, the employer and the public profit still more; the employer does not rely much who wastes half his strength at other work, nor rely on a servant who may sometimes disappoint him, by attending to other concerns. The public must gain in the increased quantity of human food produced, for without doubt an acre of land occupied by a cottager will not yield as much, at as little expense, as if it made part of a farm cultivated by a person with sufficient capital. Were all the farm servants over the kingdom paid in kind, it may be safely affirmed, from the experience of the places where this practice prevails, that the advantage would be great to themselves and to the public. The master might probably, in some cases, find it more convenient to give money, but he is far more than recompensed for any trifling disadvantage, attending that other mode, by the valuable moral habits which it is calculated to preserve. Every master who properly understands his interest will admit that he had better pay sober, honest, and industrious servants, than have those of a different description almost for nothing. From their being accustomed to pass little money through their hands, many of the farmers' servants in this county acquire such habits of saving, that they lay up a few pounds for old age, or to meet any contingency which may require more than their ordinary income."

The dwellings of the hinds are remarkably clean and comfortable; simple, but well-kept, and tastefully arranged furniture, with the invariable accompaniment of an eight-day clock, replenish the interior, whilst the climbing Honeysuckle, or delightful Rose-bush, adorns the exterior. The servants' houses are generally situated a short distance from the farm steading of which they form a part. Each hind is under the obligation of furnishing his master with an approved servant (either male or female) to work on the farm during the summer half-year, viz., from Whitsuntide to Martinmas; and should he not have a son or daughter sufficiently capable of filling this place, he must engage and maintain in his own house a sufficient *bondager* for the work—a designation which aptly expresses the onerous nature of the obligation. His wife is also required to reap 22 or more days in harvest, in payment of the house-rent.

Friendly Societies or Clubs are established by the farm servants in almost every parish, which have produced incalculable benefit to the labouring class. The affairs of these highly useful Societies are conducted by a committee annually chosen from among the members; the parish teacher generally acting as secretary and treasurer. Each Society possesses different *Funds*, as the *Cow's Fund*, *Funeral Fund*, *Sick Fund*, &c. By contributing a few pence monthly to the Cow's Fund, a member is entitled to receive from 9*l.* to 12*l.* from the Society on the natural or accidental death of his cow; provided the usual remedial measures have been resorted to for her recovery. In like manner, by paying a trifle into the Funeral Fund, on the demise of the contributor his friends or wife receive about 3*l.* to defray the funeral expenses; and an individual regularly subscribing to the Sick Fund is entitled to 10*s.* a-week for a limited period when disabled from working by indisposition.

It is remarkable that none of the landlords in Lothian, who contribute anything to the support or encouragement of these excellent rural Societies, the servants themselves endeavour to spare a few pence monthly in order to provide against the many contingencies to which their station in life subjects them. But it is evidently the interest as well as the duty of the landowners and tenants who compulsorily pay the poor-rates in Scotland to encourage Societies whose natural tendency is to keep the labourer above the necessity of applying for parochial aid.—*Sinclair.*

TREATMENT OF FARM-HORSES & LIVE-STOCK.

I will proceed to detail the feeding of our horses and the supposed treatment of our cattle and sheep. They are never turned out, nor do they receive any Grain but Oats, or Clover-hay—except a small portion during the interval between green-crops and root-crops. In summer they are fed in mangers on Wheat-straw chaff, cut one-eighth of an inch, and Tares, Lucerne, or green Rye, cut also into chaff the same size, adding ground Beans, Oats, or meal with Linseed. In winter, our Carrots, Swedes, and Mangold, will be well washed, passed through Gardner's Turnip-cutter, and again passed through a toothed cutter machine, so as to become what I call root-chaff; it will then be mixed with very fine Wheat, Bean, or Oat-straw chaff, and a little ground Beans, Barley, or Oatmeal, soaked Linseed, steamed Potatoes, and a little salt, varying the food as much as possible to stimulate their feeding. In fact, to sum up, we shall present their food in the form occupying the smallest possible compass and requiring the least mastication. Every half-hour saved in feeding is so much added to their rest—a most important ingredient in fattening. The dry chaff will prevent laxity and flatulence, producing also a sufficient and healthy excitation of the stomach, whilst it will afford to the gastric juices a ready access to every part of the mass of food. This mixture appears by its various constituents perfectly adapted to the formation of bone, muscle, fat, and flesh, all which are essential to the perfect development of a well-fatted animal. On this subject I annex, by permission, the very kind opinion of Mr. C. R. Bree.

Our horses have a plump muscularity and vigorous rotundity, proving what I said before, that their food contains every necessary element; they thrive wonderfully and cost but little—they get their breakfast, dinner, and supper, in perfect quiet. This is better than sending them for a ten-mile walk morning and evening, thus depriving them of six hours' rest; their skins are soft and their coats glossy—their general appearance exhibiting health, strength, and content. In this all visitors to my farm agree. Were it not for their daily labour, I have no doubt they would be excessively fat; therefore I am justified in anticipating a similar result for my bullocks and sheep. The least they plough is one acre per day, seven inches deep for each pair, and occasionally one and a half acres, particularly during harvest. One pair also trench or subsoil-plough one and a half acre per day during harvest, which is great work. I cannot now state exactly what number of horses we shall require permanently. I rent 45 acres adjoining my land, so that the total holding is 173 acres; we shall certainly require six at least on our principle of trench ploughing, and not resting the land. At present, owing to the great arrears of cultivation, and the various operations of subsoiling, stone-carting, &c., we have an additional four, and sharply they are worked too.

For very lean bullocks, the straw-chaff and green feed, or root-chaff, will be better than too rich a diet at first. As they freshen we shall give them richer food, and increase its quality by degrees, adding soaked Linseed, &c. Our horses and cattle will always have access to rock-salt. I apprehend in bullocks as in horses, a change from very poor to stimulating diet would be hazardous without a previous preparation by physic.

As I said in my former letters, there should be warmth, cleanliness, ventilation, and good grooming; bricked floors set in cement and well drained, appear well adapted for cattle generally. They should occasionally be washed down with sulphuric acid and water, or sprinkled with gypsum. This will convert the offensive ammonia into an efficient manure. All stables and cattle-rooms, should have their walls and ceilings lime-washed at least once a year—the mangers occasionally well scrubbed. A harness room in stables is indispensable.

My farm-yard will not look like one, for not much loose straw will be seen—a little straw-chaff may appear, here and there, to absorb the moisture and excrement from the cattle; but the solid part will be removed daily, or frequently, to the roofed tank, so as to go on the land, as rich as possible, fermented; but not rotted by rain, or evaporated by sunshine or wind. The rest of my straw, both Wheat, Bean, and Oat, will be converted as chaff into food for my stock and so go to the land in the shape of mutton, beef, or pasture for the following bond and straw for my barns. In conclusion, it will afford me very great pleasure to receive hints from so eminent a practical man on the subject of this letter.—*To J. Mechi, 4, Leadenhall-street, London, August, 1844.*

P.S.—Cost per week of keeping each farm-horse in high condition and full working order:—

Twenty-four bushels of Wheat-straw chaff, cut one-eighth of an inch, at 2*d.*	4 0
Twelve bushels of green Tares cut into chaff, at 2*d.*	2 0
Four and a half pecks of Beans, crushed into small pieces	2 3
Pollard	1 0
Cutting chaff	0 6
Straw for litter	0 0
	9 9

I value my Wheat-straw at 6*d.* per truss of 36 lbs. or 18*s.* per load of 36 trusses, which is the average price it could be sold for on the farm. My green tares I value at 1*s.* per rod, or 8*l.* per acre. Of course where Lucerne, Clover, or Rye are used, a due regard will be had to preserve the same relative cost. In winter a proportionate quantity of roots will be substituted for green food. I believe it is seldom accurately known what farm-horses do cost. I have asked the question frequently, and received for answer a shrug of the shoulders, or a shake of the head as to its worth "A great deal too much." A great fair farmer and clever valuer told me, the farm-horses ate up one-fourth the produce of the farm; that is, 25 acres out of every 100. My own calculation was 20 acres; but he is no doubt right on average lands.

A gentleman writes me, that cutting hay very fine caused irritation and griping amongst farm-horses, which he attributes to want of mastication; since he had it cut 1½ inch, no such injurious effect has been experienced. On our own farm, during several months' experience, our fine-cut food has caused no injury, probably owing to our using so a large proportion of straw chaff and little or no hay. I beg to refer to my fifth letter for other particulars of my cattle management. I think, generally speaking, a loose box, with just room for the animal to turn in, is better than stalls—although I have not practically compared the two—nor can I say from experience, whether the total absence of light is more injurious to the animal's health than any increase in its fattening. I should consider both light and air are necessary to health. Mr. Warnes's pamphlet (Longmans and Co.), contains useful information on fattening cattle. The Rev. J. C. Blair Warren, of Horkesley Hall, near Colchester, applies the close box system with judgment and advantage, and is in other respects a scientific practical farmer.

Extract of a Letter from Mr. C. R. Bree.—With regard to your question about the application of Wheat-straw chaff in the function of nutrition, I have much pleasure in offering you my opinion. Wheat-straw contains very little albumen—according to Playfair none. It therefore can be of no use in supplying the nitrogenous elements of muscle. But as you supply this in your green food, and more particularly in the Beans, its absence in the straw can be of little importance. It will, however, have the same effect when given as you do, as vegetables have often been eaten by human beings with meat. It will be useful in the following objects:—

1. In supplying the phosphate of lime to form the earthy part of bone.

2. It will assist in the formation of muscle by supplying the non-azotised portions of the structure.

3. It will supply carbon in abundance. If this carbon is not required for the restoration of waste, it will assist in forming a supply of carbonic acid in the performance of the function of respiration, and the supply of animal heat.

4. By this appropriation it will permit the excess of carbon, taken in with the other food to unite chemically with the elements of water, and thus be deposited in the system as fat. Straw, chemically speaking, differs from hay, in (*A.*) containing little or no albumen. *B.* In containing rather more organic matter. *C.* Hay leaves as much again of ashes after incineration.

I consider your union of straw with green food and Beans as sound in theory. Beans have *per se* too much albumen for animal food; by uniting straw with them you counteract the effects of this excess, and by adding green food, you supply saline matter, which is indispensable to the due performance of the function of nutrition. I think your plan judicious as well as scientific.

Home Correspondence.

Non-interference with Politics.—Before the close of the first year of your Paper, I find you departing from *your own* principle of *non-interference* with *politics*, and giving notice that in your next Number you shall test the merits of the arable and pasture system, on the principle of the labourer having a right to *employment*, as *his inheritance*. Surely this is a political question; and let me put one question to you on that subject:—Supposing the higher grades of society are determined to eat bread made of foreign Wheat, and drink beer and spirits made of foreign Barley, and that their horses shall eat foreign Oats, and their tables foreign beef, and their ships shall convey foreign provision—and let me tell you, *this is surely simply the case*—under what principle of right or justice can *you* expect the owner of the land to produce what nobody will buy, or, what amounts to the same thing, will not pay for cultivation? Why should the land-owner be obliged to produce Wheat, which he cannot sell but at a loss? And how is the labourer's right to be enforced on owners of the land, whose market is destroyed? Are they to be obliged to sell and mortgage to mill-owners, cotton-spinners, and other trade and craftsmen, all their inheritance, to pay for labour which does them no good, but makes them poorer still? Answer this question, if you please, and not argue pasture and arable on a wrong foundation, or principles that will not bear dividing (tested with truth).—*C. Kent, December 10.*

The criterion by which we have estimated the propriety of any system of cultivation is not *only* its capability of giving employment to the labourer—as our correspondent appears to think. Our words were as follow:—"We maintain that the merits of any system of cultivation depend not merely on *the profit to the cultivator and the quantity of food* which it produces, but also on *the quantity of employment it provides for the labourer.*"

These are the principles by which we propose and have endeavoured to test the systems of pasture and arable culture—their *profitableness*, and productiveness of food and *employment*—not one only, but all three. It will be observed that *only such* an additional employment of labourers as will be *profitable* to the farmer is insisted on as due from the farmer; surely it needs not many words to commend such a sentiment as that to the mind of any one. With reference to our correspondent's allegation, that in considering this subject we are breaking our own rule of non-interference with politics, we answer, by saying that the profits, the produce, and the expenses of cultivation are the very essence of *agricultural practice*.

[We have received a communication on this subject from "W. L." (we are unable to decipher the name or we would give it at length), which we hope will excuse our not publishing, as it is not our wish to enter on a discussion on the *moral* aspect of this question. Independently of any *duty* in the matter, we may safely rest our case on the *expediency* of the practice we have advocated; and to this, as regards the interest of landlord and tenant, we now invite the attention of correspondents; as, the more clearly this is exhibited, the more, it is presumable, will employment from this source be provided for agricultural labourers—a consideration which all must heartily desire, whatever difference of opinion may exist as to the modes in which it may be best effected.]

Experiments on Nutrition.—In reply to your question, in your postscript, I beg to say that an examination of the excrements of the cows, if not of their analysis as given by Boussingault, confirms me in the opinion that the unsuitableness of the food to the digestive organs had much to do with the subsequent emaciation of the cows, for I perceive that with the Mangold Wurzel there was only about 76 lbs. of dry excrement in 14 days, whilst with the Potatoes there was 187 lbs., and with the hay 339 lbs. Now it is a curious fact that the loss or gain of weight bears a very strict relation in an inverse ratio to the amount of dry excrement.

	Weight of Dry Excrement.	Loss of Weight by Cows.
On the Mangold Wurzel diet,	76 lbs.	149 lbs.
		Gain of Weight
On the Hay diet	339 lbs.	111 lbs.
		Loss of Weight
On the Potato diet	187 lbs.	78 lbs.

Now, though this relation is somewhat curious, and greatly supports my theory, yet I do not mean to insist that it altogether proves that the loss of weight is owing to the deficiency of dry nutriment, though it might be as much justified in so doing as the Duke himself is in asserting that the loss and gain of weight of the cows are owing to the deficiency of fat in the food. Now, if this theory is correct, may we not, on the other hand, on account of about three and a half times as much of fat, produce a pound of fat. We do not, on the other hand, on account of about three and a half times as much of fat, produce a pound of fat with 100 lbs. of hay, as with 100 lbs. of Mangold Wurzel in the 14 days; with the Mangold Wurzel diet, in the same period, it amounted to only 1½ lb., or half that quantity. Now, when we consider the importance of the phosphates in the animal economy, that they enter into the composition of flesh and bone, and also into the brain and nervous system, we cannot be surprised that great debility should arise from their absence in the food, or that this debility should be best remedied by giving food in which phosphates most largely abound, such as hay. The same observations may also probably apply to the other inorganic constituents, for we know that there must have been at least double the quantity taken with the hay than with the Mangold Wurzel. The superior feeding properties of [illegible] Wurzel have been fully proved, as in the experiments [illegible], by the careful and well-conducted experiments of Mr. Colman. The practical result corresponds in every way with the chemical analysis of the different roots. The cows became both in flesh and fat as we should anticipate; if we look to the [illegible] as the only source of the fat in the animal, it is impossible that fat ready formed in the food can be essential for the formation of that in the animal, since for the fat in the system [illegible] case, without destroying the animal, that the fat of the body is formed from the sugar, starch, and other unazotised constituents of the food consumed in respiration. [illegible] theory does better explains than the other the variations of the heifers and the food consumed in hot countries and in cold ones, both in man and animals, and its connexion to associate it with the fattening properties peculiar to sugar and starch.—*W. C. Spooner, Rothampton.*

[Our readers will have noticed that our correspondent's criticism of Boussingault's experiments (see p. 548) were founded precisely on that view of the subject on which Dr. Playfair himself last week (see p. 542) recorded his condemnatory notice of them.]

Gypsum.—If "W. C." will refer to my first short notice on the action of gypsum as a [illegible] manure, by which he will be able to ascertain the proper quantity of gypsum required for any given quantity of manure. It appears, from direct experiment, that 200 grains of pulverised gypsum will readily fix between 30 and 70 grains of carbonate of ammonia, but it appears that, as the result of calculation founded upon experiments, the average yield of manure which is sufficiently decomposed to be put upon land has been, during the [illegible] about [illegible] of carbonate of ammonia. It will therefore be seen that under the [illegible] mentioned, to add to every [illegible] pulverised gypsum will [illegible] of carbonate of ammonia. By [illegible] I mean by spreading to a [illegible] the quantities [illegible] per acre of gypsum [illegible] [illegible] (mixing). Let the dunghill be situated [illegible] made. Let, in the first instance, [illegible] manure [illegible] about the yard till half [illegible] deposited. Then mix them in three layers of gypsum, of which the [illegible] will [illegible] 1d. per yard of manure; mixing [illegible] 1 lb. of sulphuric acid for each [illegible] small cart-load in the heap will be less than 3d. per [illegible] load, so that the cost for 10 cart-loads, or 20 [illegible] yards, will be about 5s. The trade-price of the quantity of sulphate of ammonia, which will be furnished to the land by the gypsum and sulphuric acid in these 10 cart-loads, when entire decomposition and neutralisation has been effected, is about 1*l.* 7*s.* The covering of earth used by "W. C." tends but little to fix ammonia in any case, and will be quite unnecessary now.—*J. B. Reade.*

Hand Threshing Machine.—I have been trying a hand threshing machine, made by an ingenious mechanic in this island, but I find the labour required to work it is very great, as is the case with those I have seen in England. Will you favour me with your opinion as to the effect in lightening the labour of a windlass with rope and compound pulleys; the rope and pulleys mounted on shears 20 feet high over a sunk pit, what weight attached to these pulleys would equal the power of a man? If you think the power applicable, I have one or two plans for obtaining speed. I am now trying a very simple form of drilling machine, which will drop three or four grains of Wheat at stated intervals, as a substitute for dibbling. I have been at some difficulty in getting it put together, from the great stupidity of the people. My drilling-machine unships, and a small hay-tedding machine can be fixed to the same frame, and on removing this I affix my rake, and the frame also is made to carry a tub and drilled box for liquid manure; the shafts which belong to my large roller are removable, and are those I attach to this piece of all-work. It appears to me that this drill will be very useful both for Wheat and Turnips, and that the machine would be a great accommodation to farmers of small means, as the whole is of trifling expense, from its simplicity of construction.—*A Subscriber from the first—Jersey.*

Manure versus *Good Cultivation.*—I am convinced that it is much more important to attend to the latter than to the former of these two means of improvement; and that national, as well as individual wealth, may be more increased by the latter of the two; for I am convinced, that nothing like the full extent of the inherent powers of the soil is taken hold of by our generally too superficial method of cultivation. Good cultivation consists mainly in, 1st. Thorough-draining, which soon changes the nature and texture of the soil for the better, to double the depth that is ploughed. 2d. Deep cultivation with the plough, and not omitting subsoil-ploughing, if it be but four or six inches in depth; a little is better than none. And, 3d. Moving the soil, or fallowing well; giving unremitting diligence to move and pulverise the soil on every opportunity, but more especially in summer and in dry weather; taking care to have a good depth of soil at the finish.—*A Leicestershire Farmer.*

Sea Buckthorn, Rabbits, &c.—I am much obliged by the attention of "M. D. P." to my inquiry. What I was more particularly desirous of ascertaining was, whether the plant in question will grow equally well in inland districts; and whether it is available for any purpose as underwood. Withering states that cows refuse it, but that horses, sheep, and goats, eat it. He does not, however, notice that it is free from the attack of rabbits as "M. D. P." assures us it is. Can "M. D. P." or any other correspondent, furnish us with a list of plants which are not liable (especially when young or newly-planted) to injury from these troublesome pests; and are, at the same time, useful as underwood and cover? Do rabbits attack the Berberis aquifolium? I am told that they avoid even the wood Laurel: a list of useful plants, that are certainly safe from this destructive creature, would be acceptable to planters, as the effects of [illegible] operations are [illegible] temporary only; notwithstanding such [illegible] [illegible] hundreds of fine [illegible] plantations were last year entirely [illegible] to prevent the [illegible] of young plantation, [illegible]—*An Old Subscriber.*

Canterbury Corn Show.—[illegible] the [illegible] forwarding cut, had a very uniform appearance. [illegible] the rye, at the time [illegible] cut, [illegible] [illegible] result as that which you obtained when the crop was harvested. In some of the patches the steeped is only the finest of the unsteeped. Now, if the [illegible] first appearance when growing, surely [illegible] the ear must have indicated this great [illegible] to a considerable extent last season. When the [illegible] came [illegible] into ear, the steeped portion [illegible] superiority; but I was disappointed at harvest, [illegible] more so in the field, as the produce of one [illegible] with steeped seed yielded one bushel less than [illegible] with unsteeped seed. And this hap-

pened even while the former evidently yielded the greatest amount of straw, and counted the greater number of shoots—this in the case of Oats. In the case of Barley the superiority was not only apparent, but real, in favour of the steeped portion. In case of your former Number, I observed the description of a method for deterring thrushes from visiting any particular field, by strewing there [illegible] some particular substance offensive to [illegible]. Could you inform me what that substance is? [illegible] would [illegible] and very desirous of trying it. My [illegible] [illegible] from [illegible] much destroyed by a [illegible] [illegible] who himself has left this [illegible] for the purpose of [illegible] his [illegible] [illegible] [illegible]

P.M., his Grace the Duke of Richmond, K.G., President, in the chair. The following members were present:—The Marquis of Downshire, Earl Spencer, Col. Challoner, Dr. Hamel, Rev. James Linton, Sir Robert Price, Bart., Capt. Randolph, Professor Simonds, Mr. R. Smythies, Sir Harry Verney, Bart., and Messrs. S. Almack, W. Astbury, John Almack, D. Barclay, M.P., Thomas Raymond Barker, H. Blagrave, M. R. Bodman, John Beck, S. Wood Blake, John Partridge Bonsfield Barclay, Thomas Bennett, H. Wm. Bentinck, Captain Barclay, E. H. Baldock, R. W. Baker, G. Barnard, A. J. Brown, S. R. Colvile, M.P., Mathew Culmer, John Clover, George Cottam, Ap. W. Crowch, Robert Cobb, F. C. Cherry, Joseph Dance, Samuel Druce, R. Davey, James Dean, John Ellman, Thomas Ellman, R. Edgington, P. Fearnhead, Thomas Fowler, R. Fulcher, William Greaves, H. J. Gould, John Griffith, G. Griffin, W. H. Hyett, W. Hankin, W. Fisher Hobbs, W. Holbech, C. Wren Hoskyns, C. Hillyard, H. Holding, Thomas Jones, John Kinder, George Kilby, Fielder King, Thomas Knight, John Mantle, Edward Rickford, William Miles, M.P., Thomas Mount, Richard Milward, W. Marden, Charles North, H. Overman, A. Ogilvie, Henry Paget, Joseph Parker, C. W. H. Potter, H. Priest, J. Allen Ridgwood, R. A. Slaney, Thomas Stone, Alsiby H. Saville, William Stone, Richard Smith, J. Sealey, W. P. Salter, Hon. Villiers Shelley, M. H. Shuttleworth, William Shaw, E. Reynolds Solly, Samuel Solly, W. Sperling, H. Smith, J. Holt Stanway, J. H. Turner, C. J. Tower, Thomas Turner, John Thompson, W. Trinder, J. C. Thorpe, Thomas Umbers, John Wood, and J. A. Williams.

The Secretary, by direction of the President, read the Report of the Council to the General Meeting:—

REPORT.—The Council have again the satisfaction of reporting to the Members, at their present General Meeting, the effective state of the Society in every branch of its operations, and the continued influx of new members from all parts of the kingdom. The communications of practical results in farming, furnished by correspondents from the various localities of the country, and again disseminated among the Members by means of the Journal; the increasing extent and importance of the Annual Country Meetings, at which not only the agricultural community have the immediate advantages of personal communication and mutual interchange of experience on farming topics of common interest to all, but where from year to year specimens of the most approved breeds of cattle are in succession submitted to their notice, and the most important improvements made in the implements of husbandry submitted to their inspection, and their real value brought at once to the test of practical trial: form the leading points on which the Council have to congratulate the Members, as evidences of the great and advancement of the Society in the fulfilment of its various objects. In the application of science to the purposes of agriculture, as in all other arts, the Council are fully aware that the results will only be conclusive and satisfactory in proportion to the perfection of the particular science itself, whose principles are proposed for the regulation of agricultural practice. The laws of mechanics being simple and determinate, their application to the improvement of the principles on which the machines and implements of agriculture may be most economically effected, has been attended with results corresponding decisive in their character; but while the simple and well established principles of inorganic chemistry may with confidence be expected to serve as safe guides in leading us to a knowledge of the properties of every variety of soil, and the means of their required modification to particular objects, they can only throw light to be thrown upon agriculture by organic chemistry, a less perfect branch of the science, upon its principles received with greater diffidence, though it ultimately promises the most important results. The Council are convinced that the perfection of agriculture as a science, or farming as an art, is only to be attained by the establishment of scientific principles derived from practice, and their judicious application under the given circumstances and conditions of each particular case of climate, soil, or aspect. While, however, they deem this caution requisite in exposition of the practical objects and character of the Society, they witness with great satisfaction the rapid advances made by the distinguished chemists of the present day in that comparatively new and inviting branch of chemical philosophy connected with investigations into the laws of organic matter and the principles of vegetable life; and they have to congratulate the Society on the zeal with which their consulting chemist, Dr. Playfair, has entered this new and valuable field of scientific inquiry, and the kindness with which he has gratified and favored the members, on the occasion of their quarterly meeting, with two highly interesting lectures, elucidating the application of the most recent discoveries of chemical science to the practical operations of agriculture. The Council feel, that if any circumstance could enhance the obligations under which they are already placed by these lectures, they would be the readiness with which Dr. Playfair, at very short notice, and sometimes under personal inconvenience, prepared himself for their delivery, and the liberality with which the Royal Institution of Great Britain at once placed their theatre at the disposal of the Society for the occasion. The Society's recent country meeting at Southampton was most successful in every department of its arrangements, and fulfilled the most sanguine expectations of the Council. The extent of the show-yard, and the number of entries for exhibition on that occasion exceeded those of any previous meeting; and the trial of implements, so dependent on circumstances for failure or success, was conducted to the satisfaction of the stewards of the department and the exhibitors whose implements were submitted for trial, and proved an object of much attraction to the numerous spectators by whom it was witnessed. The success, in a financial point of view, of the meeting, was materially owing to the liberality placed at the disposal of the Council by the committee of the town and neighbourhood of Southampton in the contribution of £1000 to the funds of the Society for the purpose of meeting the expenses of the occasion. To the mayor, corporation, and authorities of the borough, the local committee, the commissioners of police, the proprietors of the trial ground, and the Southampton and Netley Railway Company, the Society, before leaving Southampton, conveyed by unanimous resolutions their most acknowledgments of the essential services which those parties, by their cordial and zealous co-operation, had respectively rendered to the Council in promoting the objects of the meeting. From the agricultural character of the district in which the next Annual Country Meeting of the Society at Shrewsbury is appointed to be held, the Council anticipate with confidence a result no less gratifying than that obtained at Southampton; and they have already taken the requisite steps in preparation for that meeting, and have also decided that the judges of stock shall be appointed from recommendations made by the members of the Society at large at the General Meeting in May.

The Finance Committee will lay before the meeting the balance-sheets of the accounts as examined and approved by the auditors on the part of the Society. Their chairman will also report to the members the large amount of arrears of subscription discharged during the past half year, as well as the mode proposed for facilitating the future collection of subscriptions. Since the last half-yearly meeting upwards of 300 new members have been elected, and the Society now consists of the following members:—Life Governors, 97; Annual Governors, 208; Annual Members, 6037; Life Members, 470; Honorary Members, 15; making a total of 6827 members on the list of the Society at the present time. The Council have unanimously requested Mr. Pusey to accept the office of a trustee of the Society, vacant by the death of the Duke of Grafton, and have elected Mr. Thomas Lockley Meire, of Cound Arbour, near Shrewsbury, a member of the Council, in the place of the late Mr. Edward Gough, of Gravel Hill, near Shrewsbury. The increasing importance attached by the members to the possession of the Society's Journal, has led the Journal Committee to continue its best consideration of the means by which the distribution of each publication may be effected with the greatest certainty, and least loss of time, among the members throughout the kingdom; and they trust that this desirable object will gradually become attained, as the addresses of members are more accurately known, and the most convenient modes of transmission to them more distinctly ascertained. For the convenience of members availing themselves of their privileges of attending the rooms of the Society, the Council have ordered a catalogue of the library, and an inventory of the implements, models, &c., to be prepared for their reference. Four years having elapsed since the date of the charter, and the bye-laws then framed agreeably with the new powers conferred upon the Society, the Council have been desirous of rendering the experience gained during this period available for the regulation of their proceedings; and they have accordingly made a complete revision of their former bye-laws, and enacted a code of bye-laws and regulations, not only embodying the tenor of such of their special resolutions as had a permanent operation, but rendering the whole more exactly in accordance with the provisions of the charter. A printed copy of these bye-laws was appended to the journal on its last publication, and thus brought under the immediate notice of the members.

The Council, in conclusion, beg to congratulate the members on the present sound and vigorous condition under which the Society is steadily advancing in the gradual fulfilment of its national objects; and, supported as it is by the continued accession of new members, they hope to extend annually its sphere of usefulness.—By order of the Council, (Signed) JAMES HUDSON, Sec.

On the motion of Mr. SAMUEL DRUCE, seconded by Mr. TOWER, this report was unanimously received and adopted. Mr. RAYMOND BARKER, chairman of the Finance Committee, then read to the meeting the following balance-sheets as audited on the previous day:—

I.—GENERAL STATEMENT OF ACCOUNT FROM 30th JUNE, 1843, TO 30th JUNE, 1844.—*Receipts.*

Balance in the hands of the bankers, Dec. 31, 1843	£2067 11 6
Balance in the hands of the secretary, 30th Jan. 1844	17 0 0
Half-year's dividends on stock	120 0 0
Annual subscriptions of governors not to show-yards	1 1 0
Annual subscriptions of members	1 1 0
Annual subscriptions of members not to show-yards	1 1 0
Annual subscriptions of members	1 1 0
Sale of Journal	1 1 0
Sale of cottage tracts	1 1 0
Sundry receipts during last year & bad debts recovered	1 1 0
Payments made to Society by Royal Agricultural College	1 1 0
Payments by C. C. Cotman, Esq.	1 1 0
Payments by Messrs. Bramah	1 1 0
Payments by Messrs. Clayton & Shuttleworth	1 1 0
Payments by Messrs. Ransomes	1 1 0
Payments by Messrs. Garrett	1 1 0
Payments by Messrs. Crosskill	1 1 0
Payments by Messrs. Hornsby	1 1 0
Payments by Messrs. Smith	1 1 0
Payments by Messrs. Wood	1 1 0
Payments by Messrs. Bentall	1 1 0
Payments by Messrs. Coleman	1 1 0
Payments by Messrs. Hall	1 1 0
Payments by Messrs. Morton	1 1 0
Payments by Messrs. Pain	1 1 0
Payments by Messrs. Ransome

spirit seems to have been infused into our Society, Sir H. Davy was invited to apply his chemical knowledge to the means of increasing the production of food. His views on this subject have not hitherto been surpassed in utility, although they are greatly undervalued by the disciples of foreign empirics. In the application of electricity to chemical analysis, Sir Humphrey took the lead, after his predecessor Ritter had through his national love of mysticism become bewildered in the mazes of Mesmerism. The prominent position which Sir Humphry attained in this path of science has been nobly maintained by his pupil Farady, who is looked up to by all nations as the first authority in electrolytic science. His idea that electrical attraction and chemical affinity are one and the same, first occurred to Sir Humphry, in consequence of his decomposition of the alkalies by electricity. The exceptions to this rule may admit of explanation, and do not militate against its general application. On this important subject much remains to be investigated. Mr. Solly hailed with great delight the prospect of a permanent connection between the Society and the Royal Institution, for the purpose of examining the nature and composition of the objects of agriculture; but, as a reason for caution against placing unlimited confidence in chemical analyses for the purpose of ascertaining the nutriment essentially required by plants, Mr. Solly mentioned the obvious difference in their nature, produced by difference of soil. This is particularly observable in Grasses, which are frequently refused by cattle when manured by their own dung; but the same cause does not render them distasteful to animals of a different species. In Norway the excrement of horses is greedily devoured by cows. Mr. Solly mentioned that some of the large and more profitable Grasses seem to prefer a great depth of loose soil, particularly of leaf-mould: therefore some of them flourish with the greatest luxuriance on the banks of hedges. This is particularly the case with the Holcus avenaceous, highly recommended by German writers of the last century. Mr. Solly exhibited some remarkable specimens of other indigenous Grasses obtained from hedge-banks in Hertfordshire—the Bromus giganteus and the Festuca elatior—the height of the former exceeded 8 feet, that of the latter was more than 6. This Grass has been particularly recommended for cultivation in the "Transactions of the Swedish Agricultural Society." Mr. Solly then seconded Mr. Miles's motion, which was carried unanimously.

Sir Harry Verney rose, to propose the thanks of the meeting to the Finance Committee and the Auditors of Accounts, on the part of the Society, for their great care of the financial interests of the Society; and the motion being seconded by Mr. Richard Milward, was carried unanimously.

Colonel Challoner returned thanks on the part of the Finance Committee, for the good opinion entertained of them and the auditors. He had the gratification to state, that the accounts were in a state of perfect regularity,—a circumstance of the greatest importance, for unless the financial department be regulated with the utmost precision, no Society could expect to prosper.

Mr. Knight, as one of the auditors, on the part of the Society, returned thanks to the meeting on behalf of himself and his colleague, Mr. Hampden Turner, who on the day previously had with him audited the accounts then laid on the table before the members. He had the satisfaction of bearing his testimony to the extreme accuracy of the accounts of the Society, which were kept in so excellent a state that it had become a most pleasing duty to audit them.

Sir Harry Verney suggested the desirableness of connecting the Society with the different local Societies throughout the kingdom, in the same manner as had been effected with great success by the Royal Agricultural Improvement Society of Ireland, where that Society was proving, not as in England, a boon to agriculture alone, but a national blessing in promoting a good understanding among all parties connected more or less with the cultivation of the soil within the range of its progress and influence.

The noble President would not fail to bring Sir Harry Verney's proposition before the Council on the earliest occasion; at the same time he thought that the movement, in reference to any alliance, such as that proposed, ought to originate with the local Societies themselves towards the Royal Agricultural Society as the central body, whose collected information they already received, and diffused with so much practical advantage throughout their respective districts.

The Marquis of Downshire bore testimony to the value of the local Societies in Ireland, and the united desire now manifested by the owners and occupiers in that part of the kingdom to go on cordially together hand in hand in the great work of agricultural improvement, to which they were invited and encouraged by the example set them in England and Scotland.

On the motion of Earl Spencer, seconded by Mr. Hillyard, a vote of thanks was carried by acclamation to the noble President.

The Duke of Richmond expressed himself grateful for the manner in which the meeting had received the proposition of his noble friend, Lord Spencer. He had at present done little, since he had again come into the office of their president, to deserve their thanks; but he confidently hoped that he should leave the Society in as flourishing a state as they had then the gratification of finding it. The Society had not only done great good already, but would do still more; and as long as it was supported by the tenants and practical farmers of the country, there could be no doubt of its continued prosperity and success. The noble duke then left the chair, and the meeting broke up.

The Meetings of the Council stand adjourned over the Christmas recess to the 5th of February.

SMITHFIELD CLUB SHOW.

We omitted mentioning in our report last week of this Exhibition, a model of farm-buildings, exhibited by Mr. Crosskill, of Beverley, his agricultural labours, to the merits of which, we understand, he has many testimonials.

Miscellaneous.

Fibrous Covering, or Gurneyism.—Fibrous covering requires to be applied in given quantities; if too much was laid on it would, like too large a dose of manure, destroy vegetation; and if too little, it would produce no very sensible action; this was a point of some importance, as an experiment would fail from either of these causes. He thought, judging from the result of experiment, that about 20 lbs. of long straw should be laid equally over a customary land-yard or rood of growing Grass, either in a lay-field or an after Grass. Previously to the next meeting, he hoped they would rake off the covering, and carefully notice the effect produced in the growth of the herbage, as compared to that in the other parts of the field; the nature and kind of Grass should also be carefully examined. Before he sat down it might be well for him to say that about seven weeks since he had covered half a field of Grass of three acres in this manner, and that about a fortnight ago when examined, the increase had been found to be at the rate of upwards of 5000 lbs. per acre over the other part of the field. At the same time the straw was raked off and laid in rows about 12 ft. apart on the field; 115 sheep were now put into the field, with a view to eat it down as quickly as possible. After they had been there about a week, they were succeeded by 26 bullocks to eat off the long Grass remaining, and which the sheep had left; the field was eaten as bare as possible. The same straw was now again thrown over the same portion of the field from which it had been raked; on inspection that morning he had found the action going on under it as powerfully as on the former occasion. He said he thought the sheep, on first raking off the straw, were not so fond of the Grass as they were of that uncovered: but after 24 hours' exposure to the sun and air, he thought they rather preferred it. He had upwards of 40 acres now under the operation, and in consequence of it, he had had Grass when his neighbours had none. He would consider it a personal favour if they would make some experiments on this subject before their next meeting.—*Mr. Gurney, at the June Meeting of the East Cornwall Experimental Club.*

Value of Guano.—Dr. Ure quotes African as varying in composition as follows:—

Moisture	from 21	to 36	per cent.
Ammonia	„ 5	10	„
Organic matter	„ 35	50	„
Phosphate of lime	„ 23	35	„
Phosphate of magnesia and ammonia	3	6	„
Alkaline salts	„ 1.5	5	„
Sand, &c.	„ 1	2	„

Now, the moisture is worth nothing, so that a sample giving 36 per cent. moisture, will contain but 64 solid guano, and that more or less damaged. Ammonia is the most valuable ingredient, and may be estimated (in comparison with other manures) at 6*d.* to 8*d.* per lb.; so that two samples, in other respects equal, one containing 10, the other only 5 per cent. of ammonia—the first will be worth 2*s.* 6*d.* per cwt., or 2*l.* 10*s.* per ton, more than the other. The ingredient next in value is the phosphate of lime, including that of magnesia, which are here in a much more readily soluble state than in bones; and taking bones to average half their weight of phosphate, may be valued at double the price of bone-dust, that is, taking bone-dust at 18*s.* per quarter of 3 cwt., the phosphates in guano may be valued at 12*s.* per cwt., or 1½*d.* per lb. But these phosphates do not decay; and hence the more the ammonia and organic matters are rotted away, the richer is the remainder in phosphates. For instance, if fresh guano contains 15 per cent. phosphates, and then loses 1-4th by decay, the whole 15 of phosphates remain in the 75 lbs. residue; and 100 of such residue will contain 20. So that decayed guano becomes richer in phosphates as it loses ammonia; the one going, in some degree, to compensate the loss of the other. The organic matters, free from ammonia and nitrogen, are the other elements in the worth of guano, and are the more valuable from their state of intimate composition with the ammonia and phosphates. In this state they may be worth 1*s.* (or more) per cwt. The alkaline salts are in such small quantity, that it may be better to simplify the calculation by omitting them. The value of guano may then be estimated according to its contents, in—1. Ammonia; 2. Phosphates; 3. Organic matter. For example, take two samples of African guano, No. 1 fine; No. 2 inferior; containing as follows, per 100lbs.:—

	No. 1.		No. 2.	
	lbs.	*s. d.*	lbs.	*s. d.*
Moisture (no value)	20		32	
Ammonia, at 6*d.*	8	4 0	5	2 6
Phosphates, 1½*d.*	25	3 1½	20	2 6
Organic matter 1*s.* per cwt.	40	8 4	23	6 8
		7 5½		6 6

Their proportionate values will be about as 7*s.* 6*d.* to 6*s.* 6*d.*: their actual prices depending, of course, on the state of the market, but still bearing the same proportions.—*J. Prideaux, in the Farmers' Journal.*

Drill.—The principle of thin drilling is admitted by every farmer who hoes his Turnips, and every gardener who pricks out his bed of seedling Cabbage-plants. The grain crops alone seem, by some prejudiced persons, to be considered capable of taking care of themselves, and are supposed to be safely allowed to carry on a vegetable agrarian war in their own ranks, during the earlier period of their growth, until two-thirds of them are killed outright, and the rest stunted or predisposed to disease, by their constitutions having been impaired in this desperate struggle for existence. If a farmer were to turn 20 sheep into a field of Turnips capable of fattening only 10, with a view to get the 10 best ones fatted, to the starving of the remainder, some of his relations would, if he were rich, immediately get him declared insane. But this is precisely the course taken with his Wheat-plants by the man who drills above a bushel per acre.—*Mark Lane Gazette.*

Notices to Correspondents.

Rural Chemistry.—Dr. E. Solly, Esq., F.R.S., Experimental Chemist to the Horticultural Society of London, Honorary Member of the Royal Agricultural Society, and Lecturer on Chemistry at the Royal Institution, may be had of all booksellers, price 4*s.* 6*d.*

Books.—*Mallins.*—"Johnston's Lectures on Agricultural Chemistry and Geology."

Cape of Good Hope.—*Broadway.*—We are unable to assist you.

Churn.—*Philla.*—The Sussex churn is a short barrel churn. It is made of block tin, which is not injurious to the butter.

Coltsfoot.—*Mallins.*—Your only remedy is perseverance in cutting off its flowers in spring, and its leaves in summer.

Decomposition of Manure.—*Subscriber.*—Lime will, perhaps, effect the decomposition of your compost within the time by turning it over once a fortnight, and shaking it all to fine pieces.

Dr. Yelloly's Forks.—*H.* would take it as a great favour if Mr. Dixon, Witham, would give us for our Paper such a description of Dr. Yelloly's forks as would enable him to have some made.

Farm-yard Litter.—*Tertius.*—Coach used as litter will not all perish; such a use of it would render the after application of the manure dangerous.

Fences.—*X. Z.*—Beech makes the best fences on the soil and in the situation you describe. The plants should be 1 foot apart in two rows 24 inches apart. Your questions about iron wire cannot be answered, except in the advertising columns.

Flax.—*J. H. Dickson.*—Your article has been received, but we are unable to give it immediate insertion.

Gas, Lime, &c.—*G. B. M.*—Pray excuse a postponement of answers to your questions till next week.

Guano.—*G. B.*—See *Miscellaneous* section.

Guanevism.—*Melksham.*—See *Miscellaneous* section of this day's Paper. That paragraph contains all we know on the subject. Can any of our Cornwall readers give us the details of this practice?

Horse Beans.—*Cymro.*—Utilize the *Berkshire* Horse-bean in any of the deep clay soils that will have. Its produce may be from 4 to 5 quarters per acre. It is not nearly so exhausting a crop as other pea crops. For Bean culture, see an early Number of this periodical.

Pages of the Gardeners' Chronicle.—We have received very many kind suggestions, some will be adopted at the beginning of the year; others cannot, for practical reasons.

Smithfield Market.—*A Subscriber.*—Your letter shall be inserted as soon as possible.

Sundries.—*Anon.*—You may safely buy your stock of bones now; but however much you may be disposed to have returns to be satisfied with the arrangement, from what we apprehend, declares against putting 2,000 bushels down in any one lot. Your Beans may be sown at the rate of from 2 to 3 bushels per acre; the first day's experience will tell you how many to make the folds; it of course depends almost entirely on the nature of the crop. The White Norfolk Turnip should be all eaten by this time; you should next have Rye-grass for February, then Swedes till April, and lastly Mangel Wurzel.

Sulphate of Magnesia.—*David.*—The use of this salt is one of the best means you have of getting this alkaline earth *into* plants. We cannot say, what effect it may have on Borrel. The suggestion to which you refer, was not ours.

Warne's Suggestions for Preventing Cattle.—*Constant Reader.*—Apologies are due both to you and Mr. Sproule for our misapprehension of your meaning. The pamphlet is published by Edwards and Hughes, Ave-Maria-lane.

*** As usual, many communications have been received too late.

Markets.

SMITHFIELD, Monday, Dec 18.—Per stone of 8 lbs.

Best Scots, Herefords, &c.	4*s.* 4	to 4*s.* 8	Best Downed & Hall-breds	4*s.* 8	to 5*s.* 0	
Best Short Horns	4 0	4 4	Best Long-wools	3 10	4 2	
Second quality Beasts	3 8	4 0	Ewes and second quality	3 0	3 8	
Calves	3 8	4 4	Pigs	3 0	4 0	

Beasts, 3713; Sheep, 26,970; Calves, 111; Pigs, 803.

To-day is our annual "Great Market," and one better supplied has not been known for many years. The scarcity of keep during the season, and the general fallingaway quality of the supply for several months past, had induced the belief that good fleet would have been scarce on this occasion: in consequence an expectation had been formed by those who made extra exertions to supply the anticipated deficiency, that there would meet with a fair remuneration for their skill and quality of capital; we are sorry to record a serious disappointment. A more splendid collection of cattle we do not remember ever winnessing. Our tabular statement refers to the prices obtained for general average quality. Anything approaching to the quality of Prize Cattle would, in some instances, make rather more, as meeting the fancy of the buyer to make a show; and in some instances very big Beasts were unselling, in consequence of the change of weather, and scarcely made 4*s.* 4*d.* A very large quantity was bought by country butchers, so that London is not so full of Meat as might be expected from the numbers exhibited, and opens a little better prospect for the future. During the early part of the day very little was sold; towards the close a little more briskness was observed, but still great numbers were turned out unsold—several of very good quality, but the greater part second rate. The supply of Sheep pens very large, and for the most part of good quality. The general trade is very heavy indeed; as with the Beasts, there were several of superior quality amongst the Sheep which made considerably more than stated in our Table; for instance, we noticed some particularly fine Downs, weighing about 30 stone of 8 lbs, which realised 8*l.* each. Some few lots of old Downs made nearly 5*s.* 6*d*; but 5*s.* 4*d* per 8 lbs is the more general price. A few lots of Long-wools also made 5*s.* 4*d.* Second quality were very unsaleable, and many of that description turned out. We had a good show of Veal, but trade heavy at our quotations. Pork-trade was very bad, which is usual at the break of a frost.

Friday, Dec. 20.

Our supplies of foreign Beasts is not very large to-day, but with those left over from Monday are quite enough for the demand. There is a difficulty to dispose of the very big Beasts, although the rather favourable change in the weather has caused a little briskness amongst the good selling qualities:—Monday's quotations are fully supported for this description. Some of the largest Oxen are losing money, even from what was bid on Monday, and we fear they will not all be sold. Trade is very bad amongst the Sheep; those that are not pretty good are scarcely saleable. Ewes make very little money. There has been a great glut of dead Meat since Monday, which makes the butchers very cautious about buying to-day. The best qualities are making about the same price as Monday. Veal-trade is very heavy; it must be a very good Calf to make 4*s.* 4*d* per 8 lbs. Second quality is very low, prices ranging from 3*s.* 8*d* to 4*s.* 0*d*. Pork-trade is still bad, at the same prices as on Monday.

Beasts, 1819; Sheep, 9180; Calves, 146; Pigs, 294.

Sl, West Smithfield.

HOPS, Friday, Dec. 20.

The Market continues firm, holders expecting better prices after Christmas (above): there has been some rather extensive sales of bags during the week. Pine Pockets are very scarce.

Pattenden & Smith, Hop-Factors.

WOOL.—British, Friday, Dec. 20.

The Market continues quite as active as we last reported it. The demand for some descriptions of sorted Wools has increased, consequently sales have been effected at improved rates. Manufacturers complain that the prices of goods are far from adequate to the advanced rates of the raw material.

James Perrin, Wool Broker.

POTATOES.—SOUTHWARK WATERSIDE, Dec. 16.

The contrary winds have continued through the past week, which has prevented the arrivals of Potatoes from all countries, consequently there are only a few small lots in the Market for sale, and they maintain fully the advanced prices, the particulars of which we annexed in our last report.

COVENT GARDEN, Dec. 21.—Notwithstanding the unsteady state of the weather the market has been tolerably well supplied with most articles during the week, but trade has not been brisk. Among fruit there has been little alteration since last week. Pine-apples are sufficient for the demand, and are offered at nearly the same prices as quoted in our last report. Grapes have not altered in price; good samples are worth about 2s. per pound. The best dessert Apples at present in market are the Blenheim Pippin, Ribston Pippin, and Court of Wick. Of Pears, the principal sorts for table are, at present, Nelis, Glout Morceau, and Passe Colmar. These are, however, not so good as they are in some seasons, being, comparatively speaking, gritty, and not well flavoured. All kinds of Nuts are scarce. Filberts are very dear. Good samples bringing from 140s. to 150s. per 100 lbs. Oranges are plentiful. Among vegetables scarcely any difference has taken place since our last report. Good samples of Seakale and Asparagus are offered at last week's prices. White Cowcoll is excellent, and the purple sort is also good. Cauliflowers are scarce. Turnips and Carrots of good quality are selling at the same prices as last week. Celery, although good has suffered a little from the effects of the frost. Tomatoes may still be had, but they are very scarce. Brussels Sprouts, Savoys, and other Winter Greens are good in quality, and the supply is equal to the demand. Our flowers chiefly consist of Cyclopedian Heaths and roseums, Epacrises, Gaultheas, Chorozemas, Amaryllises, Azaleas, Ixias, Narcissus, Chrysanthemums, Tulips, and Roses.

FRUIT.

Pine Apple, per lb.	2s to 7s	Oranges, per dozen	6d to 1s 6d

Salsafy, per bunch	1s to 1s 6d		

MARK-LANE, Monday, Dec. 16.

The supply of Wheat by land carriage coastwise this morning was moderate; both qualities and prices the same as on the terms of last week, but great difficulty was experienced in the disposal of secondary and inferior descriptions, of which some quantity remained unsold. Foreign very maintains its value, but the sale continues limited. We observe no alteration in the value of Barley, Malts, and Peas from this day se'nnight. The quantity of Oats is very small, and large arrivals expected. Dealers were averse from purchasing; but extreme prices were obtained from consumers and necessitous buyers.

FRIDAY, Dec. 20.

The arrivals of all Corn during the week have been small, and business, both on Wednesday and to-day, very limited. Great difficulty is experienced in realising the English Wheat left over from Monday; foreign is wanted by the millers, who are restrained by its comparatively high value from purchasing. Barley and Beans are unaltered, but the return of frost induces factors to hold their White Peas for an advance. The market continues very bare of Oats, and where sales are effected, a slight advance is obtained.

NOW PUBLISHING, IN QUARTERLY VOLUMES,

THE WORKS OF G. P. R. JAMES, ESQ.

Price 6s. cloth, handsomely printed in medium octavo, and illustrated.

This new and attractive Series of Mr. JAMES's Works commenced on the 1st of July with the "GIPSY," and was followed on the 1st of October by "MARY OF BURGUNDY." The future Volumes will be published Quarterly, each containing a complete Work.

VOL. III., CONTAINING THE

HUGUENOTS: A Tale of the French Protestants,

WILL BE PUBLISHED ON THE 1st OF JANUARY,

And will contain, in addition to the usual Illustration, a new and highly-finished Portrait of the Author; to be inserted as the Plate promised in the First Volume, to form a Frontispiece to the Series.

LONDON: SMITH, ELDER, AND CO., 65, CORNHILL. EDINBURGH: BELL AND BRADFUTE.
DUBLIN: J. CUMMING.

PUNCH'S ALMANACK FOR 1845

Will be introduced to the Public on the 24th instant. One of the most prominent features of the ALMANACK will be

A PICTORIAL CHRONOLOGY FOR 1844;

ILLUSTRATIVE OF

THE IRISH STATE TRIALS.
THE PROGRESS OF THE DOG BILL.
THE INTRODUCTION OF THE POLKA.
ART UNION AND FINE ART DISTRIBUTION.
THE RUNNING REIN FRAUD.
VISIT OF THE EMPEROR OF RUSSIA.
THE WAR IN MOROCCO.
AGRICULTURAL ASSOCIATION.
THE WRIT OF ERROR.
THE VISIT OF LOUIS-PHILIPPE.
COMPLETION OF THE ROYAL EXCHANGE.
THE TRIUMPHS OF PUNCH.

In addition to these Artistic wonders, "PUNCH" has also depicted the following

BUBBLES OF THE YEAR:

THE O'CONNELL RENT.
"SHAVING THE LADIES"
CHEAP CLOTHING.
TOM THUMB AT THE PALACE.
TESTIMONIALS TO MANAGERS.
PATENT LIFE PILLS.
CHEAP FURNITURE.
THE AGRICULTURAL PRIZE LABOURER.
BRITISH AND FOREIGN DESTITUTE.
YOUNG ENGLAND'S SOIREE.
THE GREAT UNACCOUNTABLE
FASHIONABLE PROPRIETARY CHAPELS.

This arrangement will insure Merriment to everybody's Christmas, for something less than the cost of an ordinary Mince Pie viz., 3d., or 4d. stamped.

OFFICE FOR PUBLICATION, 194, STRAND.

Price SIXPENCE, free by post SEVENPENCE.

The Lancet,

Of Saturday last, DECEMBER 14, contains:—

A COURSE of LECTURES on ORGANIC CHEMISTRY, delivered during the Winter Session, 1844, in the University of Glasgow, by JUSTUS LIEBIG.—Cyanogen and its Compounds continued—Metallic Cyanides—Paracyanogen.

FOREIGN DEPARTMENT:—Italy, Scientific Congress at Milan—Indian Corn a cause of Pellagra—Fibrin of the Blood in Inflammation—New Method for the Analysis of the Blood—Scurvy.

ORIGINAL PAPERS:—On the Theory of Menstruation. By G. F. Girdwood, Esq.—The late Cases of Poisoning by Prussic Acid. By H. Letheby, M.B.—A Substitute for Wood Engraving.—Facts and Observations Illustrative of the Nature and Treatment of the Diseases of Women, with Remarks on some Subjects connected with Midwifery. By G. Oakley Heming, M.D., F.L.S.—On the Treatment of Femoral Hernia. By J. Sebastian Wilkinson, Esq.—On the Labours of Graduated Doctors in the Country. By R. Hodgson, Esq.

BRITISH MEDICAL JOURNALS:—The Origin of Puerperal Fever—On the use of Nitric Acid as an Escharotic in certain Hæmorrhoidal Affections—A case of difficulty in recognising the Sex of an Infant—Cases of Fractured Skull.—Death from Impaction of a portion of Barley "Haw" under the Tongue.

CHEMISTRY, PHARMACY, AND MATERIA MEDICA:—Adulterations:—Scammony.

The New Medical Incorporation—The solid Trunk of the Profession without the Offsets and Parasites—The consent of the Society of Apothecaries of London to occupy a position in the Incorporation of the General Practitioners of England and Wales.

The Inconsistencies which the Government has manifested in forming the Plan for what, in the New Medical Bill, is called a "Council of Health"—The proper Objects of such an Institution—The Pest House in Bridge street, Blackfriars.

The desire of the General Practitioners of England to see the Legally Qualified Medical Men of Ireland and Scotland placed on a footing of professional equality with themselves.

REVIEWS:—Facts and Observations in Medicine and Surgery, having particular reference to Fractures and Dislocations, Gunshot Wounds, Calculus, Insanity, Epilepsy, Hydrocephalus, the Therapeutic application of Galvanism, and Fibrinous Diarrhœa. By John Grantham, F.R.C.S.

THE GOVERNMENT MEDICAL BILL:—Meetings of the Medical Profession.

HOSPITAL REPORTS:—Guy's Hospital—Cases furnished by the Clinical Report Society—Idiopathic Tetanus—Exhibition of Extract of Indian Hemp—Death.

MISCELLANEOUS LETTERS.

News of the Week, &c. &c.

London: JOHN CHURCHILL, Princes-street, Soho; and to be had of all Booksellers and Newsvenders.

Price SIXPENCE, free by post.

The Railway Chronicle

Of SATURDAY last, DECEMBER 14, contains,

SOUTH WESTERN EXTENSIONS—INCREASE in RETURNS—LIVERPOOL and MANCHESTER and GRAND JUNCTION AMALGAMATION — GOVERNMENT TAX — NEW FORM of BILL PROPOSED by BOARD OF TRADE—POLICY of ESTABLISHED RAILWAYS.

REPORTS OF MEETINGS—Liverpool and Manchester, with the Directors' Report—Grand Junction, with the Directors' Report—Lancaster and Preston Junction—London and South-Western, with the Directors' Report—Eastern Union, with the Director's and Engineers' Reports—Rickinder's Report on the Newry and Enniskillen Line.

PROJECTED LINES—Aberdeen—West Riding Junctions—Shrewsbury, Oswestry, Ruabon and Chester—Gloucester and Dean Forest—Wilts, Somerset and Weymouth.

VALUE OF SHARES—Returns from London, Liverpool, Manchester, Leeds, York, Hull, with Comments on the respective Markets, and latest Prices.

PARIS MARKET.

RAILWAY LITERATURE—Simm's Practical Tunnelling, as exemplified in the Bleckinsley and Saltwood Tunnels.

MISCELLANEOUS—Law Proceedings—Hardship of Signing Parliamentary Deeds—Birmingham and Gloucester—Opening of the Norwich and Leamington—Accident on Brickiayers' Arms Branch.

CALLS, CONTRACTS, LOANS, TRAFFIC TABLES, &c.

Order The Railway Chronicle of any Newsvender.

LOANS.—TO FARMERS AND OTHERS.—The sum of 20,000*l.*, and several smaller amounts not less than 150*l.*, to be advanced upon Leasehold or Freehold Property, Reversions, Money in the Funds, Annuities, Life Interests and good Personal Security, or upon Assignment of Farm Stock.

Apply to Mr. MULLINS, St. Michael's Chambers, St. Michael's-alley, near the Royal Exchange, Cornhill, London; if personally, between the hours of 11 and 3 o'Clock. Letters pre-paid.

CONTENTS of the NUMBER for SATURDAY last, DECEMBER 14, OF

THE ATHENÆUM,

JOURNAL OF ENGLISH AND FOREIGN LITERATURE, SCIENCE, AND THE FINE ARTS.

Twenty-four Large Quarto Pages, Price FOURPENCE, Or Stamped, to go free by post, 5d.

Reviews OF, WITH EXTRACTS FROM—

The Reformers before the Reformation, by E. de Bonnechose
Sketches of the Reformation, by the Rev. J. Hewels
Life and Rebellion of James Duke of Monmouth, by Geo. Roberts
The British Almanac
WITH SHORTER NOTICES OF—
Historical Parallel between the English and French Revolution, by M. le Comte Maxime de Choiseul Daillecourt
The Public and the Medical Profession
The Blind Man and his Guide
Night Voices and other Poems, by H. Spicer
Ballads and Lays from Scottish History, by N. Clyne, M.A.

Order The Athenæum of any Bookseller or Newsman.

Saturday, Jan. 4, 1845, will be published, pr. 6d., Stamped, No. 1 of THE UNITED GARDENERS' AND LAND STEWARDS' JOURNAL, the profits of which will be devoted to the Relief of Aged and Indigent Gardeners and Land Stewards, their Widows and Orphans. To be Edited by Mr. MARNOCK. All Donations, Subscriptions, and Communications to be addressed to the Editor, at the Royal Botanic Gardens, Regent's Park. The Journal will be printed by Messrs. Whittelly Brothers and Co., Peterborough-court, 135, Fleet-street, where Prospectuses may be obtained on application.

This day is published, price 2s.,

AGRICULTURE; its Practice with Profit, elucidated by a Contrast of Oriental and British Usages, in a Correspondence with the Royal Agricultural Society of England. By HENRY NEWNHAM.

In this Correspondence, the Employment of the Agricultural Poor is considered, with reference to an Asiatic principle of adjusting the Wages of Predial Labour. Second Edition, with Notes and Additions.

London: Published by ROAKE AND VARTY, 21, Strand.

On Thursday, Dec. 12th, will be published, by Mr. WM. SMITH, 113, Fleet-street,

A SYSTEM of CULTIVATING CUCUMBERS in MILLS'S IMPROVED PIT, so arranged as to be heated with hot water, by BURRIDGE and HEALY'S Boiler and Tanks. With a Descriptive Plate. It will be a Supplement to the Second Edition of Mr. MILLS'S Work on the Culture of Cucumbers and Melons.

On the 1st of February will be published,

A TREATISE on the IMPROVED CULTIVATION of PINE-APPLES. By G. MILLS. With Diagrams of a Hothouse and a Pit for that purpose; with Plan of Apparatus for Heating them with Hot Water on the Tank System.

ON SATURDAY, THE 4TH OF JANUARY, 1845,

Will be Published, Stamped for free transmission by post, price Sixpence (to be continued Weekly),

No. I. of

AN ORIGINAL JOURNAL

OF

FAMILY EVENTS, NATIONAL AND PRIVATE BIOGRAPHY, LIFE AND HEALTH, AND GENERAL NEWS.

TO BE CALLED THE

HISTORICAL REGISTER

UNDER THE SANCTION, AND WITH THE ASSISTANCE, OF VARIOUS

Government Departments.

THE importance to the welfare of society of the three great events of Human Life—

Birth, Marriage, and Death,

has led the Government to establish a Public Department for their Registration. In order to carry out the same views more extensively and usefully, **The Historical Register**, *under the sanction of the Registrar-General* and *various Public Departments*, will lay before the public, every Week, a comprehensive, accurate, and well-digested Register of such events, and all the interesting circumstances connected with them.

The Conductors of **The Historical Register** have the satisfaction of announcing, that, to accomplish this object, the most complete arrangements have been organised with the official Registrars of Births, Marriages, and Deaths, throughout England and Wales.

With BIRTH and MARRIAGE the associations are obviously many, important, and interesting; and it is only necessary here to state that **The Historical Register** will be a most extensive record of such events, and of all matters incidental to them which interest the Public.

With DEATH is associated one of the most important features of **The Historical Register**, viz.

National Biography

Of all persons, of any distinction whatever, their friends wish for some Biographical Memoir; of all eminent men, the nation requires a Biography: there is, however, at present, no publication which furnishes this information systematically,—which gratifies public curiosity at the time it is excited; and there are very few in which, at any time, are found accounts of more than a mere fraction of the interesting lives which should be recorded. This, therefore, is an entirely new field, which **The Historical Register** is about to occupy. It will give full and accurate

Biographies of all Public Characters, and shorter Memoirs of Private Persons of Worth and local mark.

Social, as distinguished from *Political* Life, has hitherto had no journal to record and discuss the numerous circumstances tending to its advancement or retarding its progress. **The Historical Register** will now supply this want.

Historical Events will be recorded briefly, clearly, and impartially; in such a manner that **The Historical Register** may be referred to hereafter for an accurate statement of the History of the Period.

The *Literature* of the day, so far as it relates to its special topics, will come within the scope of **The Historical Register**.

The HISTORY and PERSONAL CONSTITUTION of the

Civil Departments of Government

Are now about to be treated for the first time; a History of each Public Department will be drawn up from the earliest period, and the Appointment, Resignation, and Promotion of all Functionaries will be registered from time to time as they happen. These details, of an analogous nature to the contents of the "Army List," will be compiled, *by Authority*, from authentic information.

The general character of **The Historical Register** will be best understood by a brief enumeration of the subjects which it will comprehend:—

The Registration of the Births, Marriages, and Deaths of the upper and middle classes, on a more comprehensive and systematic scale than has hitherto been attempted.
Biography—General, National, and Private.
Social Condition and Domestic Life.
The Insertion of Abstracts of Wills and Administrations of Public Interest.
Judicial Proceedings relative to Divorce, Pedigree, &c.
The Operation of the Registration Acts.
Life and Fire Insurance.
Public Health; and the various circumstances in respect of Buildings, Drainage, Ventilation, Sepulture, Epidemics, Unwholesome Employments, &c. which affect it. Information will be obtained from official and other sources respecting all Public Works for the Improvement of Towns; the Proceedings of the Health of Towns Commission, and all Societies for improving the Physical Condition of the People. The Weekly Reports of Mortality in the Metropolis, and Quarterly Reports of Health throughout England and Wales, will be published, under the authority of the Registrar-General, in THE HISTORICAL REGISTER.

In addition to the above, its own peculiar topics, **The Historical Register** will be especially a

FAMILY NEWSPAPER,

In which an ample and impartial Chronicle, *free from political party bias*, will be given of all the important Events of the Week.

It may confidently be expected that **The Historical Register** will become the especial organ for the announcement and recording of Births, Marriages and Deaths, and the chief public source in which searches after them will be made; thus investing the Journal with great genealogical value for the protection of hereditary rights.

"It is the *Personal*," says a popular writer, "that interests mankind, that fires the imagination, and wins their hearts;" and we beg the reader to bear in mind that it is to the *Personal*, distinguished from the scandalous, that **The Historical Register** mainly devotes itself.

The Historical Register will consist of 16 folio pages, or 48 columns, stamped for free transmission by post.

The Historical Register will be *arranged in four parts, so that it may be read by four persons at one time*, in a form convenient for binding and preservation.

The Historical Register will be published *every Saturday*, in time for the morning mails.—Price SIXPENCE.

☞ The FIRST NUMBER of **The Historical Register** will appear on Saturday, the 4th of January, 1845.

(Only a very limited number of Advertisements will be admitted.)

*** Announcements of Births, Marriages, and Deaths will be inserted at a very moderate rate, and a copy of **The Historical Register** will *be forwarded, without charge, to the persons making the insertions*. The clerks of large parishes, with the sanction of the clergy, receive the notices of Marriages in the Established Church; and the various Registrars throughout the Kingdom, with the sanction of the Registrar-General, receive the notices of other Marriages, and the notices of Births and Deaths.

Office for Advertisements and Communications, 7, Catherine-street, Strand, London.

Printed by WILLIAM BRADBURY, of No. 6, York-place, Stoke Newington, and FREDERICK MULLETT EVANS, of No. 7, Church-row, Stoke Newington, both in the county of Middlesex, Printers, at their Office in Lombard-st., in the precincts of Whitefriars, in the City of London; and published by them at the Office, No. 5, Charles-street, in the parish of St. Paul's, Covent-Garden, in the said county. Whereat all Advertisements and Communications are to be addressed to the Editor.—Saturday, December 21, 1844.

THE GARDENERS' CHRONICLE AND AGRICULTURAL GAZETTE.

A Stamped Newspaper of Rural Economy and General News.—The Horticultural Part Edited by Professor Lindley.

LANDSCAPE GARDENING AND GARDEN ARCHITECTURE.

MR. GLENDINNING, since his residence near the Metropolis, has had the honour to be consulted by a number of Noblemen and Gentlemen in the improvement of their Parks and Gardens, and in the construction and heating of Horticultural Buildings in the most economical as well as effectual manner. He has now made such arrangements as will enable him to devote his particular attention to these important subjects; and Noblemen and Gentlemen desirous of consulting him, are respectfully requested to address him at Chiswick Nursery, near London.

THE ARBORETUMS, QUEEN'S ELMS, BROMPTON, NEAR LONDON, AND EAST COWES PARK, ISLE OF WIGHT.

RAMSAY BROTHERS, Landscape Gardeners, Contractors for Planting, Earthwork, Road-making, Forming Ornamental Waters, and Improvers in general of Landed Property.

Plans and Estimates submitted, and works contracted for in any part of the kingdom.

Messrs. R. invite Noblemen and Gentlemen to an inspection of their choice stock of Ornamental Plants, which have been selected for the Lawn, the Parterre, and the Shrubbery, and now growing at Queen's-Elms, one mile from Hyde Park Corner.

WILLIAM MAY begs to offer the following at the very moderate prices below quoted, Catalogues of which may be had.

100 Hardy Shrubs and Ornamental Trees, in 50 sorts, for 42s.; 200 do. do., in 100 sorts, for 80s.

100 sorts showy Hardy Herbaceous Perennial Plants, for 42s.; 200 do. do. do., 80s.

100 Roses in 50 good sorts, for 25s.; 100 do. do., in 100 fine sorts, 42s.; 50 do. do., in 50 extra fine sorts, 30s.

100 select Double Hollyhocks, for 42s.; 12 do., extra fine, named, for show, 20s.

100 Gooseberries, approved varieties, in 50 sorts, for 16s.; 100 do., in 100 fine sorts, for 20s.

Seeds of Hollyhocks, from double flowers, in packets, 200 seeds, 2s. 6d.; 500 seeds, 5s. each.

Seeds of Pansies, from finest named sorts of 1844, packets, 2s. 6d. and 5s. each (seeds post free).

Forest and Fruit Trees, Greenhouse and Stove Plants, Florists' Flowers, Garden Flower Seeds, &c., comprising in each department all the leading novelties in present cultivation.

Hope Nursery, Bedale, Dec. 1844.

PERFECTION IN PEAS.—FRASER'S SHANLEY MARROW.

F. FRASER, Nursery and Seedsman, Lea Bridge-road, Essex, in offering his friends and the public the above Pea begs to assure them it has no rival, its quality being as far superior to Knight's and all other Marrows as those surpass the commoner Peas. Its height is about 5 feet, a prodigious bearer, and continues in season much longer than the usual kinds. The stock on hand is very limited. Price 7s. 6d. per quart. A remittance expected to accompany orders from unknown correspondents.

CORNISH KIDNEY POTATOES.—THE EARLIEST OF ALL EARLY POTATOES.

It is remarkable that this valuable sort should be so little known and cultivated in England. It is grown to some extent in the West of Cornwall, AND HAS BEEN PRODUCED IN THE OPEN GROUND DURING THE LAST TEN YEARS, FROM THE 15TH TO 18TH OF APRIL, (on an average.)

Upwards of three hundred acres are annually grown in the neighbourhood of Penzance; and thousands of baskets are sent, by steamers, to supply the London and Bristol Markets.

The growers obtain them so early, that they are enabled to procure an excellent second crop on the same land.

It is a most valuable sort, and should be grown in every garden where early vegetables are required.

Sold in Hampers, containing 2 and 3 gallons, at 5s. and 7s. each, package and carriage free to London or Bristol, which will be forwarded on receiving a Post-office order, on application to WILLIAM E. RENDLE, Union-road Nursery, Plymouth. December 26, 1844.

THE TRUE FASTOLFF RASPBERRY.

GREAT YARMOUTH NURSERY. NORFOLK, 1844.

PATRONISED BY HER MOST GRACIOUS MAJESTY THE QUEEN, HIS GRACE THE DUKE OF RUTLAND, HIS GRACE THE DUKE OF MARLBOROUGH, THE EARL OF HARRINGTON, THE EARL OF LIVERPOOL, THE LORD BISHOP OF LONDON, LORD VISCOUNT LORTON, LORD SONDES, &c. &c., as well as by the HORTICULTURAL SOCIETY OF LONDON.

THE Fruit of the above RASPBERRY, upon which Dr. LINDLEY pronounced his opinion, was gathered by YOUELL and Co. in the garden of Mr. Edwonds, of Scratby, in this county, whose Raspberries are well known to be far superior to what is termed the "Filby Raspberry."

The statement in last week's Paper, made by a person by name of Crisp, that Mr. H. YOUELL had gathered fruit in what he terms the Filby Garden, may be correct; but in gathering fruit of the Raspberry, it was done solely with the view of comparing it with the fruit that was being submitted to Dr. Lindley; and found, as they have before stated, to be far inferior; and it was also done with a further view of satisfying themselves that the RASPBERRY they are offering to the public, and for which YOUELL and Co. have been awarded two Certificates of Merit, by the Horticultural Society of London, is the only genuine variety. The statement is thus far void of truth, and invented for the sole purpose of puffing off the variety sent out by the agent of the Filby Gardens.

YOUELL & Co. take the present opportunity of returning their sincere thanks for the distinguished, and perhaps unparalleled patronage they have received for introducing and widely spreading throughout the United Kingdom and Continent (at a cost of between 300*l.* and 400*l.*) a most valuable fruit, which would have remained in obscurity; and at the same time they are happy to state, the extensive demand it met with, and the satisfaction it has given, have fully realised all their anticipations.

In conclusion, YOUELL and Co. deeply regret they are called upon to animadvert upon the position that one of so sacred a calling as Mr. Lucas should have placed himself in, in this affair, by authorising and permitting to be published matters of which he was perfectly ignorant, and containing an assertion utterly void of truth, that the fruit upon which Dr. Lindley pronounced his opinion was gathered in the Filby Garden.

Fine Canes of the TRUE FASTOLFF RASPBERRY can be obtained only of YOUELL and Co., or their Agents, a list of whom appeared in the *Gardeners' Chronicle* of the 7th inst.

Great Yarmouth Nursery, Dec. 23, 1844.

T. AND C. LOCKHART, Florists and Seedsmen, 156, Cheapside, London, respectfully beg to inform the Nobility and Gentry, that their List of Flower and Vegetable Seeds for the present Season will be forwarded post free, on application, together with a complete List of the most showy hardy herbaceous plants, giving their respective heights and colours.

T. and C. L. take the present opportunity to request early orders for Ranunculus and Anemones, as their unique collection will be planted by the end of January; therefore they will not be able to execute any orders received after the 25th January.

TRUE WILLCOVE BROCOLI.

WILLIAM E. RENDLE has much pleasure in announcing, that he has been fortunate in procuring a good and well-selected parcel of the

TRUE WILLCOVE BROCOLI,

a sort held in high estimation in the West of England, and considered by all who know it to be the *earliest and most valuable Brocoli* for spring use. It can be highly recommended. In sealed packets, 1s. each.

W. E. R. can also recommend the following as very choice and superior sorts of Vegetables, and ought to be cultivated in every garden.

Superior Dark Crimson Beet
Dwarf, small-top Scarlet Beet
Chapple's Cream Brocoli
Early Cornish Cabbage
Large Paignton do.
Myatt's Superb Curled Parsley
Wood's Earliest Frame Radish
Hammond's fine new White Cape Brocoli
True Drumhead Lettuce

The above at 6*d.* per packet, or the whole set, including the "WILLCOVE" BROCOLI, will be sent free by Post, for a Post-office order, value 4*s.* All other kinds of Vegetable Seeds warranted new and genuine.

Union-road Nursery, Plymouth, Dec. 28.

UNRIVALLED YELLOW DARLIA, LANGLEY'S "DUKE OF YORK." Light primrose yellow round, cupped petals, great depth, well arranged, and perfectly circular; centre, full, compact, and well up; general form and habit of "President of the West;" height 4 ft.; strong plants early in May, 10*s.* 6*d.* Discount to the trade on not less than 12 plants.

C. LANGLEY can, with the greatest confidence, warrant the above SUPERB DAHLIA "FIRST RATE," and to give general satisfaction. It will be found a valuable acquisition to every one who grows for exhibition, as it will be sure to take its place in the best stands of 6 and 12 next season, being of the most exquisite form, and as *compact as any Dahlia in cultivation.*

It has been pronounced by Mr. Glenny "very delicate," and by Mr. Bragg (Slough), to be "the completest and most promising *Dahlia* of 1843. It obtained a Certificate at the great Metropolitan Show, Sept. 25th, 1844, as a first-class flower.

Barnsley, Sept. 10. First prize, also Dr. and Mrs. Lindley's Prize.
Bretton, " 12. Best specimen, Yellow.
Kirkheaton, " 13. First prize.

The above are the only places where it has been shown.

N.B. Orders will be executed from the present time, and sent in strict priority as received. Agents in London, Messrs. Huser and Magnulsen, 4, Langham-place; and Messrs. Watkins and Watkins, 24, Cornhill.

THE FILBY OR FASTOLFF RASPBERRY.

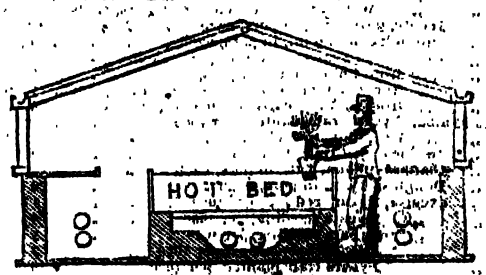
On or about July 18, 1843, Mr. HENRY YOUELL came to the garden at Filby, and requested me to give him some fruit of the above Raspberry, to send to Dr. Lindley. Mr. H. YOUELL and myself then looked over the Canes, and gathered some, he said that about two dozen would be sufficient. He then consulted me upon the best way of packing them, and I recommended him to pack them in cotton wadding or wool; to this he assented, observing that he thought it would be the best material.

Signed, WILLIAM CRISP, Gardener to Rev. C. Girdlestone.
Filby, Dec. 10, 1844. Filby, near Yarmouth, Norfolk.

SUPERB SEEDLING DAHLIA, "LORD DENMAN" (Naylli's). Colour dark claret part of the season, shaded petals, of fine texture, well arranged, good centre, round outline, an excellent flower to stand, and one of the best show flowers out, being the property of an amateur it has been shown only at Nottingham, gaining the 1st Prize.

Sent out in dry roots, 5*s.* each, by J. NAYLL, Linton, Nottingham.

EDWARD BECK informs the Public that in consequence of the greatly increased demand for his SLATE TUBS, he is enabled to reduce the price of the following sizes about 10 per cent. He regrets the too frequent delay which has occurred in the execution of orders. This he hopes to avoid in future by keeping a supply on hand.



Present Prices for Cash or Post-office order.			
14 inches	11*s.* 0*d.*	30 inches	22*s.* 6*d.*

Slate Works, Isleworth, Middlesex.

WHITNEY'S PATENT CLOTH for COVERING GREEN-HOUSES, CUCUMBER, or MELON PITS, &c. This Cloth is made expressly for the purpose of applying Whitney's Composition upon, and is much more durable than any other material: when varnished it is beautifully white and transparent. The perfect success of Whitney's Composition for all Horticultural purposes cannot be more fully established than by stating, that on the 1st of April last, a Black Hamburgh Vine was set in a border, the stem introduced into a house covered with Calico, and coated with Composition. On the 21st of Sept. a bunch of Grapes was cut weighing 1½ pounds, the fruit was finely coloured, and the flavour pronounced to be excellent. A sample was sent up to the Editor of the *Gardeners' Chronicle* for his inspection. The vine grew very luxuriantly, the foliage very fine, and the wood ripened exceedingly well. As a winter protection it is infinitely warmer than glass.

The PATENT CLOTH and COMPOSITION can be obtained of Messrs. Butler & Muckley, Covent Garden Market; Hurst & M'Mullen, Leadenhall Street; Warner & Warner, Cornhill; Barclay & Sons, Farringdon Street; and Hannay & Co., Oxford street. — Wholesale and Shipping Agent, Mr. Bailey, Wolverhampton.

HOT WATER FOR BOTTOM-HEAT.

J. WEEKS AND DAY, Manufacturers, &c., Gloucester Place, King's Road, Chelsea, HORTICULTURAL BUILDERS, and Hot-water Apparatus Manufacturers, invite the attention of Horticulturists to their Improved Plan of Bottom-Heat, now becoming so universally adopted.

From the extensive Practice they have been honoured with for 20 years in designing and building CONSERVATORIES, GREENHOUSES, HOTHOUSES, PITS, &c. &c., and erecting their HOT-WATER APPARATUS to every description of Building to which heat is applicable, J. WEEKS and DAY have the greatest confidence in recommending their BOILERS as the most efficient of any yet invented, their largest being capable of heating a range of Forcing Houses 300 feet in length, with a comparatively small quantity of fuel, and only requiring attention once in 12 hours. To be seen in use at most of the London Nurseries, also at their Manufactory; and a variety of Horticultural Erections, Models, Plans, &c. &c.

STEPHENSON AMES, CO., 61, Gracechurch-street, London, and 17, New Park-street, Southwark, Inventors and Manufacturers of the Improved CONICAL and DOUBLE CYLINDRICAL BOILERS, respectfully solicit the attention of scientific Horticulturists to their much approved method of applying the Tank system to Pineries, Propagating Houses, &c., by which atmospheric heat as well as bottom-heat is secured to any required degree without the aid of pipes or ducts. S. A. Co. have also to state that the segment of numerous friends they are now making their Boilers of iron as well as Copper, by which the cost is reduced. These Boilers, which are now so well known, scarcely require description, but to those who have not seen them in operation, prospectuses will be forwarded as well as reference of the highest authority, or they may be seen at most of the Nobility's seats and principal Nurseries throughout the kingdom.

J. & C. beg to inform the Trade that their Manufactory in New Park-st., every article required for the construction of Horticultural Buildings, as well as for heating them, may be obtained upon the most advantageous terms. Conservatories, &c. of iron or wood, erected upon the most fashionable designs. Balconies, Palisading, Field and Garden, Wire Work, &c. &c.

PETER LAWSON AND SON,
Seedsmen and Nurserymen to the Highland and Agricultural Society of Scotland.
AGENTS.—Messrs. W. and J. NOBLE, Seedsmen, 152, Fleet-street, London.
Edinburgh, Nov , 1844.

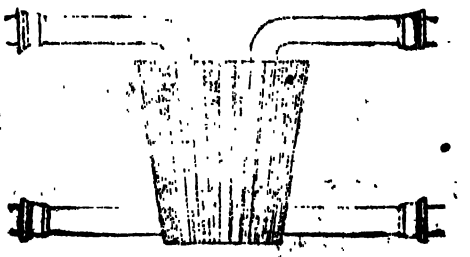
TO BE DISPOSED OF, FIFTY FRUITING AND EIGHTY SUCCESSION QUEEN PINE PLANTS.
For Particulars, direct A. GREGORY, Gatton Park, Reigate, Surrey.

HOT-WATER APPARATUS FOR HEATING HORTICULTURAL BUILDINGS, DWELLING-HOUSES, CHURCHES, and MANUFACTORIES, upon improved principles, and at very moderate charges, erected by DANIEL and EDWARD BAILEY, 272, HOLBORN.

D. and E. BAILEY having devoted much time to the consideration of this subject, and had much experience in the erection of apparatus for the above-mentioned purposes, have, by improvements suggested in their practice, rendered their mode of heating not only very efficient, but very simple, and have combined durability in the apparatus with economy in the charge. They have erected apparatus in England, Scotland, and Ireland, for many noblemen and gentlemen, and have had the honour to be employed by the Horticultural Society of London, in executing the works of their splendid Conservatory, lately erected at Chiswick.

D. and E. BAILEY also construct in metal all descriptions of Horticultural Buildings and Sashes, and invite noblemen, gentlemen, and the public to an inspection of their various drawings and models, at 272, Holborn, where they have the opportunity of exhibiting, amongst other metal works, an extremely complete and convenient kitchen apparatus, or range, adapted for the continued supply of hot water, and an arrangement of the oven more complete than has hitherto been brought before the public.

D. and E. BAILEY were the first to introduce metallic curvilinear houses to horticulturists, and can refer to the Conservatory attached to the Pantheon as one of their works, besides many others in this country and on the Continent.



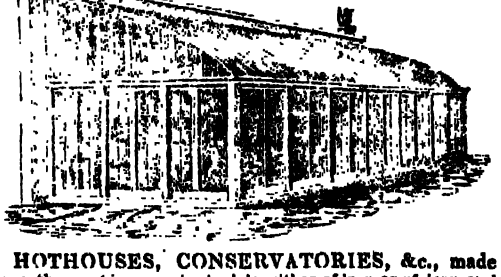
D. and E. BAILEY have prepared a quantity of the Galvanic Plant Protectors, which are now ready for immediate delivery; they beg to introduce to public notice a new Trough Pipe, for Orchidaceous or other Houses where vapour is constantly, or at intervals required, and which may be seen at their Manufactory.

DRAINING OF LAND.—THE WORKMAN'S LEVEL, invented by MR. BAILEY DENTON, is made and sold, as approved by him, by Messrs. JONES, Opticians, 30, Lower Holborn, London, price 30s.

CONICAL BOILERS.—The Boilers invented by JOHN ROGERS, Esq., are made of several sizes, and may be obtained of JOHN SHAWEN, Ironmonger, Sevenoaks, Kent.

They may be seen in operation at Messrs. Chandler's, Vauxhall; Loddiges', Hackney; Henderson's, Pine-apple-place, Edgware-road; Rollisson's, Tooting; Penny's, Plymouth; The Horticultural Society's Gardens, Chiswick; and in the Gardens of the Royal Botanical Society, Regent's-park.

BURSIDGE AND HEALY'S NEW BOILER and FURNACE for HORTICULTURAL PURPOSES.
Registered under 6 & 7 Vict., Cap. 65.
No. 130, FLEET STREET, LONDON.



BURSIDGE and HEALY respectfully inform the Horticultural Public that they have constantly on hand an extensive assortment of their new Boiler and Furnace Doors. In very numerous cases where they have been fixed, they have the highest testimonials of their complete success: for the further assurance of those who may require this apparatus, BURSIDGE and HEALY refer them to the Horticultural Society's Gardens, Chiswick; also to Mr. GLENDINNING, Garden Architect, &c. &c., Chiswick Nursery, in the same neighbourhood, where the apparatus may be seen in successful operation, in connection with their new Tanks. The following are the present prices:—

Plain Boiler.			Patent Door and Frames, Fire-bars & Dead Plate.		Flue Door.		Damper.		Will heat of Pipe.	Forcing Pit, Length by feet.
in.	ft.	s.	s.	d.	s.	d.	s.	d.		
10	1	8	20		7	6	6	2	6	80 feet.	12 to 20
Ribbed Boiler.										
10	2	2	20		10	6	7	6	2	6	50 to 70 ft. 4 in.	Under 25 to 40
12	2	15	30		12	6	7	6	3	6	80 to 125 feet.	40 to 65
14	3	10	35		17	6	8	6	4	6	150 to 250 feet.	65 to 100
18	5	5	42		25	0	8	6	5	6	300 to 400 feet.	Warm a grapery 35ft. long, and a pit 30ft.
24	8	15	50		35	0	8	6	7	6	600 to 800 feet.	

If 3-inch pipe be used, one-third more. If 2-inch pipe, as much more.

The above quantities are rough estimates, which may be varied by enlarging or contracting the fire, or by regulating the fire door. It is possible to heat a much larger quantity of pipe with the boiler, but it would be done at great loss of fuel. The above proportions can be generally relied on as a near approximation to what is correct.

COTTAM AND HALLEN, ENGINEERS, IRON-FOUNDERS, &c., &c., No. 2, WINSLEY-STREET, OXFORD-STREET, LONDON, and at CORNWALL ROAD, LAMBETH.

HOTHOUSES, CONSERVATORIES, &c., made upon the most improved principle, either of iron or of iron and wood combined, which can be fixed complete in any part of the Kingdom, at very low prices.

HOT-WATER APPARATUS for heating Hothouses, Conservatories, and Greenhouses; Churches, Public or Private Buildings, &c., with COTTAM'S PATENT or ROGERS'S BOILERS. After 15 years' experience, and having fixed upwards of 2000 Apparatus for the above-mentioned purposes, and by various improvements which they have made during that time, C. and H. can with confidence undertake the erection of similar Apparatus upon the most extensive scale.

Materials may be had for those who wish to fix their own Apparatus.

THE TANK SYSTEM on an improved principle, that will heat the house at the same time, without pipes.

IRON HURDLES, best Wire for Strained Fencing, Ornamental Iron and Wire-work, Garden Chairs, &c., &c., and every description of Implement for AGRICULTURAL and HORTICULTURAL PURPOSES.

Show Rooms at their Manufactory, 2, Winsley-street, Oxford-street, where a large assortment of the above can be seen.

HOT-WATER HEATING APPARATUS.—J. PORTER begs to announce that, in addition to the many other and valuable purposes for which Galvanised Iron is peculiarly applicable, he is now manufacturing Tanks and Gutter for Vaporising, and Pipes for heating by top and bottom-heat, Hothouses, Pineries, Conservatories, &c. J. P. has also to state that, having secured the assistance of parties of the greatest skill and experience, he is prepared to furnish Plans and Estimates for Heating and Ventilating Horticultural Buildings, Public Edifices, Private Houses, Churches, Warehouses, Manufactories, &c., accompanied by references to executed works. J. P. does not profess to offer any one particular form of Boiler as the best, to the exclusion of every other, but adopts those which will insure the greatest share of efficacy and economy, in each particular case.—Grove Patent Galvanised Iron Roof and Fence Work, Southwark, second carriage turning to the right from Southwark Bridge.

GUANO (GENUINE PERUVIAN & BOLIVIAN) ON SALE, BY THE ONLY LEGAL IMPORTERS, ANTONY GIBBS AND SONS, LONDON; WM. J. MYERS AND CO., LIVERPOOL;
And by their Agents,
COTESWORTH, POWELL, AND PRYOR, LONDON; GIBBS, BRIGHT, & CO., LIVERPOOL and BRISTOL.
47, Lime-street. Dec. 21, 1844.

THE PATENT PORTABLE SUSPENSION STOVES are admirably adapted for Conservatories and Greenhouses—a pure air, combined with warmth, being as indispensable to the health of plants, as of Human Subjects. Nearly Four Thousand have been sold since the commencement of the present Season. Specimen Stoves are in operation daily, at GROSER and JOHN DEANE'S Opening to the Monument, 46, King William Street, London Bridge.

THE NOBILITY AND GENTRY desirous of increasing their collection of Stove, Greenhouse, Hardy, Herbaceous, and other Plants, Camellias, Roses, Geraniums, &c., are respectfully informed that Messrs. J. and H. Brown's Descriptive Priced Catalogue, for 1845, may be had per post on application.—Albion Nursery, Stoke Newington, London.

The Gardeners' Chronicle.

SATURDAY, DECEMBER 28, 1844

MEETINGS FOR THE TWO FOLLOWING WEEKS.

Friday,	Jan. 3	Botanical	8 P.M.
Monday,	Jan. 6	Entomological	8 P.M.
Wednesday	Jan. 8	Society of Arts	8 P.M.

Another point which Potato-growers have taken for experiment is the difference in produce where whole tubers and cut sets are employed. This is a question of no small importance, if we consider how considerable a saving of seed is effected in a bulky crop like the Potato, if we can only diminish the weight of the seed by one third.

A good many persons are in favour of using whole tubers, notwithstanding the waste of material. Our correspondent *Falcon*, says:—"I always plant WHOLE Potatoes which INSURES a tolerable crop in all seasons, preventing *dry rot* in *hot* weather, and *rottenness* in *wet*, which cut pieces are so liable to."——*A Leicestershire Farmer* says that after many years' experience he has discontinued planting cut sets and substituted whole tubers, selecting small ones, but not the smallest; he adds, that adopting this rule, he has had an excellent crop this year, and the tubers are *extraordinarily large*. They were a late sort, and planted on the 25th of April in rows 3 feet asunder, and 9 inches apart in the rows.——*Mr. White*, of Uxbridge, has, for some years past, found the advantage of setting the second size of the small Potatoes, such as are not fit for market, without cutting them (he gives the very smallest to the pigs). Having an insufficient supply of tubers of one very large sort, he was obliged to cut them in order to get enough for seed, and many failed in consequence; nevertheless, his crop brought him 18 or 19 tons per acre. While, however, many of the cut sets failed, none of those missed which were planted whole. With his letter Mr. White was so obliging as to send one of those Potatoes that yielded at the rate of 18 or 19 tons an acre; it weighed 1 lb. 14 oz., and was a large coarse sort, only fit for cattle; the eyes were very hollow, especially near the top of the tuber, where several ran into each other, forming deep indentations or fissures upwards of an inch in length.——A correspondent near *Birmingham* finds his cut sets a general failure; and another at Woodstock gives a decided preference to whole Potatoes; the poor people "having lost almost all their cut sets, while their whole Potatoes stood the long drought."

On the other hand, *F. N.* writes thus from Bidston, in Cheshire.

"At p. 267 a correspondent recommends 'the largest size Potatoes, uncut, for sets, planting them in rows one yard apart, the sets being two feet and a half from each other,' &c. This induced me to try the experiment, and up to June the large whole sets appeared to have such a decided advantage over those cut, that I mentioned it in a short article on the subject, which you introduced at page 416. I now give the result of the experiment. I gave twelve rows (*i. e.* six of each alternate cut and whole) a fair trial: the season being very dry, after their being ploughed up with a 'broad shoulder' as recommended, I had them watered with diluted liquid manure; the haulm of the whole sets grew very rank, and in accordance with your advice in a Leading Article, No. 26, page 427, I nipped the flowers off the twelve rows as they appeared, and at taking-up time was very much disappointed with the large whole set rows. Instead of having lots of large Potatoes I had lots of small ones, which were near the surface, about the size of marbles and little Apples, the haulm of which sets was very tuberous, presenting excrescences similar to small green kidney Potatoes with leaves growing from them; in short, where I got one measure from the whole sets, I got a measure and a half from the cut, off the same quantity of land; and taking into consideration that nearly one-third of the cut sets missed, I cannot but think that a field planted with good cut sets will produce a better and rounder crop than the largest whole sets ever seen."

Now, in noticing this matter we labour under the great disadvantage of having no precise statements to deal with. In all cases of experiment the result should be exactly given—not vaguely. It is not sufficient to say that one crop is *much* better, or finer than another. One desires to know *how* much. Weights and measures give results from which only one conclusion can be drawn. It is, however, clear that during the last summer opinion has in general become adverse to cut sets, and favourable to whole tubers; and this too was the general conclusion of the late Mr. Andrew Knight. We, however, have never yet seen reason to concur in this view, unless perhaps in very dry seasons like the last. Our opinion is formed upon very numerous and exact experiments in the Garden of the Horticultural Society, made some years ago, for the express purpose of testing the accuracy of Mr. Knight's theory; and as those experiments are probably but little known it may be as well to state their results in this place.

In the year 1832 five plots of ground of equal size, and as nearly as possible of equal quality, were selected for the growth of five different varieties. One half of each of these plots was planted with whole tubers and the other with sets containing but one eye each; the plants were one foot apart in the rows, and the rows themselves 18 inches apart. Upon taking up the crop it was found that the estimated results were as follows:—

	Tons.	cwt.	lbs.
Whole Tubers	113	2	72
Single Eyes	111	3	54

giving a difference in five acres of about two tons, which is hardly more than the difference between the weight of the tubers and sets originally planted.

At the time this experiment was prepared, it was thought advisable also to ascertain what difference in their rate of increase there really is between tubers and eyes, when each set or tuber has the power of growing undisturbed by its neighbours; so that the real productiveness of each could be ascertained with the greatest accuracy. In this case it was anticipated that the tubers, having full space to develope themselves, would certainly surpass the sets very materially in proportionate productiveness; but the result proved to be altogether the other way. A piece of ground was selected of quality as nearly uniform as possible; it was divided into four feet squares; and in the centre of each square was planted either a tuber, or a single eye, or a set containing three eyes, or the whole surface of a tuber pared off so as to leave the eyes safe but to remove the centre. In this experiment it was found that the rate of produce was in 13 cases out of 16, in favour of single eyes as compared with tubers; in 9 cases out of 16 in favour of single eyes as compared with sets containing three eyes; and in 10 cases in 16, in favour of single eyes as compared with parings; or, if we consider the results of the whole 16 experiments as belonging to one experiment, their proportions are expressed by the following figures.

Whole Tubers	338·38	or	2
Single Eyes	717·87	..	11
Taree Eyes	613·94	..	5
Parings	504·69	..	4

nearly.

And this conclusion corresponded with other experiments instituted with similar objects in view.

In the year 1834 a further trial was made with early Champion Potatoes, upon ground on which no Potatoes had been previously grown. No manure was employed, nor was the soil by any means in a fertile state for garden ground. The experiment was varied in four ways by planting at intervals of 30, 24, 18, 12, and 6 inches. We extract from the Society's Transactions the following tabulated return.

Distance between Rows.	Sets.	Weight planted	Weight taken up	Rate of Produce	Weight required per acre for seed	Weight produced per acre	Net return per acre, after deducting the weight originally planted
ft. in.		lb. oz	lb. oz.		lbs.	lbs	lbs tns cwt. lb.

Crop small and bad.

Nothing could well be more conclusive than this in favour of good sets with single eyes. The first and the last trials being left out of consideration, because the distances were unsuitable to the variety under experiment, those marked * are the ones to which attention must be directed, and they show so great a difference against whole sets as to leave no room for doubting which is the better method under the circumstances. It showed too, what is of no small importance to poor people, that a better result was obtained by planting 1704 lbs. than by 7426 lbs., and that when the weight planted was increased to 32,065 lbs. per acre, a great loss was sustained instead of anything being gained.

We may add that further trials in 1836 confirm the accuracy of this conclusion, the *net* produce of Potatoes set in the 1st week in March having been 14 6 19, and even 17 10 96 against 13 11 23. It was only when the planting was delayed till April that tubers had something the advantage of sets.

There is one point, however, that still remains to clear up in this matter, and that is, whether small refuse Potatoes will not prove as advantageous as sets. Upon this we find no satisfactory evidence. By satisfactory, we mean no detailed experiments conducted with care, skilfully varied, and often repeated, the results being accurately ascertained by weighing when the crop is dry.

This, and some other matters, hereafter to be noticed, for which our correspondence furnishes us with data, we shall revert to on another occasion, before the time for planting Potatoes shall have arrived.

IVY.

In the two last Numbers some observations occur on the probability of Ivy living on walls when its connection with the ground is cut off by the destruction of the stem. The following facts may illustrate the matter, and perhaps save one of your correspondents the mortification of the loss of his evergreen.

Any visitor to Amberley Castle, in Sussex, may observe that the right-hand tower (looking toward the front of the ruins), flanking the gateway, is in better preservation than the left-hand one, particularly its battlements and upper third. These twin-towers are now destitute of Ivy, but about 35 years ago, the one above mentioned was completely clothed with it. The occupier of the Castle at that time found it necessary, in making a gangway in the moat round the foot of this tower, toward a new-made door-way in the castle wall, to cover up the stem of the Ivy with many feet of earth and rubbish. The consequence was the suffocation of its roots and the death of the plant within a few years. As the dead branches decayed and dropped off, the masonry became exposed, and the conservative influence of its former drapery was manifest, as before said, in the more perfect condition of the battlements, and of the general aspect of the tower above its fellow, which never had any Ivy at all. Many years of exposure has now made the difference less remarkable, but it is still very striking.

When ruined walls, by the dissolution of their materials and the free admission of rain-water, assimilate to fissured rocks or the common earth, Ivy will often (as I suppose the Winchester case may be), send in auxiliary roots, which would take the place of the parent stem, and it is not uncommon to see Ivy growing sparingly and stuntedly on old walls of much thickness, as other plants will do contrary to their usual habit. But a large old plant, which has always had its main rooting in the ground, will not bear to be severed from it.—*P. P.*

NOTES ON THE TULIPS OF THE MIDLAND COUNTIES.

Having heard that there were many fine seedling and other Tulips to be seen in the Midland Counties, I, during the past blooming season, visited some of the principal beds in Staffordshire, Lancashire, Derbyshire, Leicestershire, Yorkshire, and Nottinghamshire.

Having made various memoranda at the time, I intend to lay the results of my tour before the readers of the *Chronicle*, feeling sure that notices of fine flowers, as well as good seedlings, will prove acceptable.

My first point of inspection was Derby, famed amongst the northern growers as the place where Sherwood raised his batch of seedlings, from which some fine Roses have been originated. Here I saw Lady Colville (Sherwood's), a flamed flower, but by no means first-rate; also Mrs. Darwin, of the same grower, with a broken and indistinct flame; Lady Wilmot (Sherwood's), another variety, was in splendid condition, but unfortunately has a slightly tinged cup; the beautiful bright cherry flame, joined to the perfect feather of this flower, rendered it extremely attractive; and were it not for the before-mentioned defect, it would be an extremely popular variety. Lady Crewe, Mrs. Mundy, and Lady Middleton (all Sherwood's), were in a highly beautiful state. I had heard much for and against these flowers, but, in my opinion, they were the best feathered Roses I saw during the journey. I was informed that a person, who has obtained some notoriety in writing for a floricultural publication, in an article on the Tulip, some years ago, imputed some very unworthy motives to the Derby and Nottingham growers relative to these flowers. The Derby florists are very sore on the subject; for, as I understand them, the writer is convinced of his opinion being erroneous, but has not made the *amende honorable* in the work which contains his strictures.

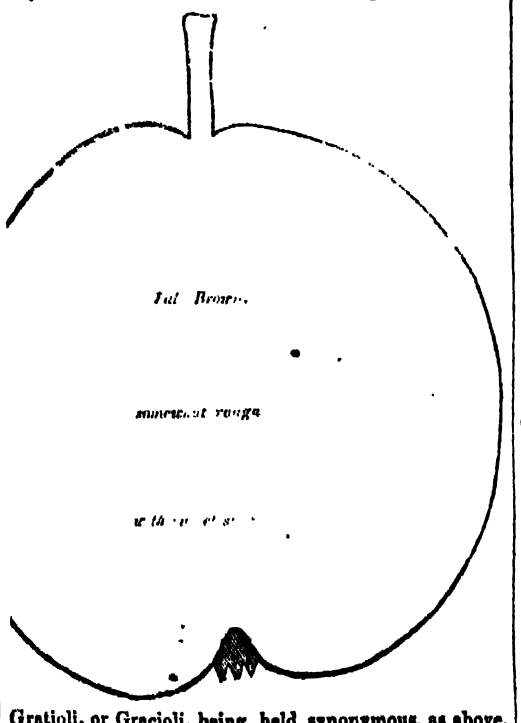
The flowers were pointed out to me, and certainly no two feathered flowers are more distinct than the Ladies Crewe and Middleton. The feathering of the former is laid on lightly, with occasional breaks in the intensity of the pencilling, in the style of an old bizarre, known as the Yorkshire Trafalgar, the colour being of a bright cherry-red, and the tops of the petals slightly inclining inwards. On the contrary, Lady Middleton has a heavy plated feather, much darker than Lady Crewe; in fact, so much so, that when the flower is old, it has often been exhibited as a byblomen, in which state I saw several blooms. The petals also, when opening, rather throw back, like Count de Virginnes; it does not, however, retain this peculiarity, but assumes a perfectly globular form, and in fact has a fine cup. Some Triomphe Royales, growing in the next row, and which were in an unusually good state, were far inferior to this splendid variety; the best strain of which, I was informed, is remarkably steady. There was yet another Rose in great plenty dispersed through the various beds, of which there were a few excellent flowers, whilst there were many which were apparently worthless. I allude to Queen Boadicea, or Duchess of Newcastle; this is much larger than any other of Sherwood's varieties, but evidently is very uncertain. In the class of bizarres, I do not think that the Derby florists are above mediocrity. I saw, however, very superb blooms of Royal Sovereign, of which they have evidently a good strain, and which ap-

pears to be plentiful in the Midland Counties. This, with Magnum Bonum, Sultana (also one of Sherwood's seedlings, of rather inferior character), and Trafalgar, appear to be the principal varieties.

In flamed bizarres they are also deficient. Captain White, with its heavy breeder beam or flame; Potter's Albion, with a tinged cup (not the Albion of the metropolis), Dutch Catafalque, Earl St. Vincent, and Polyphemus, are amongst their best. The growers here appear to be quite alive to the importance of raising seedlings from fine sorts, with clean cups and perfect shapes, and great quantities, of all ages, are coming forward, some of which were blooming, the majority being byblomens, and decidedly the best of this class that I saw was a seedling named Sarah Anne; it was a perfectly feathered flower, with the colours beautifully distinct; Washingtons are also well-grown here, with Queen Charlotte and Suble Rex which last has a stained cup; Bienfait and Lilliard Violet are amongst their best feathered byblomens, and the Norwich Black Bagot was in very good character. After looking through the most noted collections, I walked to Chellaston, a village a few miles from Derby, where a large number of seedlings are grown. Here I saw but few old varieties, but this deficiency was made up by the quantity of really fine flowers, which have become rectified, or have assumed their proper character, by breaking into colour from the breeder. Unfortunately, hundreds have been sold in the self state, and dispersed over the country without name or number, which I fear will cause irremediable confusion. I was highly pleased with the collection, as all the flowers with foul or bad-shaped cups had been removed, leaving little to condemn, but much to admire. A flamed rose called Lady Stanley was extra fine, decidedly better than Strong's Duchess of Kent. Fanny Cerito, also a flamed rose, which was first broke into colour at Nottingham, is an acquisition to this scarce class. I saw fine flowers of every colour—superbly feathered and flamed byblomens, bizarres, and roses of every shade. Having purchased a few that took my fancy, I made the best of my way to Spondon, and from thence by train to Nottingham.

The collections here contain a greater quantity of London flowers than those at Derby, though one of the most successful exhibitors, who during the last twenty years has gained one hundred pounds worth of plate, has but few. In his beds I saw large quantities of old established favourites, at least sorts that are esteemed at Nottingham; for I must not attempt to conceal the fact that several of the varieties pointed out as his pan flowers, through the above-named series of years, would not have been tolerated amongst the metropolitan growers. The sorts were, Royal Sovereign, Magnum Bonum, and Victory—*Feathered Bizarres*. Captain White, Albion (Potter's), and Lord Milton—*Flamed Bizarres*. Lilliard, Norwich Black Bagot, and Pap Bienfait—*Feathered Byblomens*. Queen Charlotte, Sable Rex, and Violet Wallers—*Flamed Byblomens*. Lady Crewe, Triomphe Royal, and Lady Middleton—*Feathered Roses*, unique. Flambeau de la Duchesse, and Turner's Lord Hill—*Flamed Roses*.

These appear to be old standards, but I learn that several are repudiated, and will not now be countenanced, as the taste of the Nottingham florists is fast assimilating to that of the south-country growers. In my inspection of the various beds I recognised the following:—Polyphemus, which I have seldom seen in better condition; Titian, Leonatus Posthumus, Lavinia, Paul Potter, Agalia, Bijou des Amateurs, Strong's Duchess of Kent, Goldham's Earl of Liverpool, Manteau Ducal, Lucullus, &c. Of the varieties peculiar to the neighbourhood I particularly noticed Plantagenet, broken from the breeder this season—a fine, heavy-feathered bizarre, perfectly clean, and equal to Royal Sovereign; Pilot, a fine cupped-flamed bizarre, in the style of Captain White, without showing the breeder colour, neither does the flame break through at the top of the petals; Prince of Wales, an extra fine-feathered byblomen, was also in the same collection; Lady Middleton (before noticed) in first-rate character; Incomparable le Grand, a flamed byblomen, an exceedingly pretty flower of rather a rosy-purple; Rider's Julile—the beam of this flamed bizarre is not very distinct, still I admired its style. Here was pointed out to me La Belle Nannette; *certainly* a very pretty flower, but as *certainly* a Triomphe Royal, though possibly possessing a superior strain.



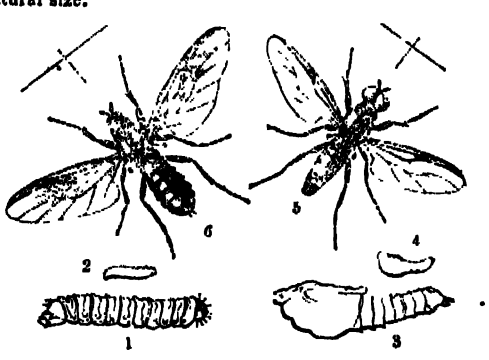
Arlette, a splendid feathered Rose; the breeder was raised, I learn, near Manchester. This was "a gem of the first-water," and though said to be tender it is a great acquisition. Rose Camellius, a pure and excellently marked flamed Rose, rather too long in the cup, and very much like Flambeau de la Duchesse. Sancta Sophia—feathered byblomen. This was broke from a breeder, raised by the same amateur who originated Arlette from seed, and most certainly was a noble flower; it was something in the way of Lawrence's Friend, though not quite so heavily feathered. This was the first that had been grown at Nottingham, and was indeed a fine variety. Lord Milton, of which I saw many strains, from the veriest rubbish to a really good flower, but the bad ones preponderate; still, as a flamed bizarre, it is a sort that will be grown. Magnum Bonum, or Sir Sidney Smith, appears to be very plentiful in the neighbourhood, and being steady, it is much thought of as a stage flower; still it bears no comparison with the blooms of Royal Sovereign and Victory, which came under my notice. Tricolors are not much cultivated; Strong's Flora, and Lawrence's Duke of Clarence, being the only two that I observed. In byblomens, Queen Charlotte is considered a first-rate flame; still it has a long cup; and in comparing it with the Derby Seedling, which had here broke in a flamed state, I most certainly think that Sarah Anne was the best of the two, the white being of great purity, and with a shorter and better cup. La Bien Aimée, a flower somewhat like Violet Alexander, was beautifully marked; it was also too long in the cup, but still is an acquisition. That delicate and singularly marked flower, Cenotaph, I saw in only one bed; it was well grown, and the violet beam up each petal was very distinct. One of the florists pointed out two London flowers—Osiris, and Duke of Devonshire—remarking what inferior sorts they were; but in the miserable specimens submitted to me, I could not recognise a trace of the features of these really two fine varieties.

Before concluding my remarks on the Nottingham Tulip beds, I may allude to a few of the breeders grown there, which are of extraordinarily fine properties, and apparently much sought after. I give their names as they were pointed out to me: *Bizarres*.—Rienzi, Comus, Invincible, Duke of Hamilton, Earl of Nottingham, and Joseph Strutt. *Byblomens*.—Lady Clifton, Madonna, Miss Longden, and Mrs. Sherwin. *Roses*.—Arlette, Amelia, Pauline, Lady Sale, Favourite, and Anastasia.—*W.*

THE JERSEY GRATIOLI.

(*Syn. Norris's Pear.*)

This is the name proposed for a most excellent variety of Pear, specimens of which were received for inspection and a name from H. W. Bucknall, Esq.; from one of which, of medium size, the accompanying representation has been made. The following communication was forwarded by Mr. Bucknall along with the fruit: "Oct. 12.—I herewith transmit you half-a-dozen Pears; I sent you the same variety about this period last year. [Noticed, *Gardeners' Chronicle*, vol. iii., p. 721.] You then said you believed it to be in cultivation in the neighbourhood of London. I have since taken great pains to ascertain the variety, without any effect; and the only tree I can learn to be in existence is one in my own neighbourhood. Are you still of opinion that you cannot determine the name of the fruit? If so, please to take particular notice of it. As a Pear cultivator, I do not hesitate to pronounce that, according to my own taste, it is the finest Pear in flavour, and in all its qualities, I ever met with. I trust these will reach you in perfection, which I think they will be in two days or so. The fruit I have chosen is of an average size; the tree is a fine old standard of 40 or 50 years, and a very free and constant bearer. I think it a great pity that the variety should not be promulgated, and I shall be very happy to be the means of extending its cultivation." Fully agreeing with the above remarks, it is presumed the notice here given will prove acceptable, although the origin of the variety cannot be satisfactorily traced; neither can the application of the name Gratioli be accounted for, as this name has been for centuries the acknowledged synonym of the Summer Bon Chrétien, a very different fruit from the one in question. The



Gratioli, or Gracioli, being held synonymous, as above, by Duhamel, Dr. Diel, and many other French and German authors, was sufficient cause for demurring in naming the fruit in 1843, as alluded to in Mr. Bucknall's letter; and more especially as the name of Gratioli had only been heard indistinctly and casually applied to the present variety. But, according to Mr. Langelier, who is well acquainted with this fruit, it is cultivated in Jersey under the name of Gratioli. This being the case, it has been considered proper to designate it as the Jersey Gratioli, in order to prevent its being confused with the Summer Bon Chrétien, which of course it otherwise would. It is also called Norris's Pear, from having of late been extensively cultivated by Mr. Norris, one of the greatest fruit-growers in the neighbourhood of London. The fruit is regularly formed; the eye is in a very even depression, open, the segments of the calyx standing outright; flesh melting, like honey, exceedingly rich. It, however, continues but a short time in perfection, as is generally the case with early Pears. In its decay it does not become mealy or insipid, but still retains its honied nature. Its season is October. The tree grows vigorous, with erect, dark-brown shoots. The buds are rather obtuse and hoary. Leaves ovate-oblong, shortly acuminate.—*R. T.*

ENTOMOLOGY.

Dilophus febrilis.—(*The Fever-fly.*)—The economy of this insect is very similar to that of the Bibio marci, which was recently described in this Journal, and the perfect insects are nearly related. It was named *febrilis* by Linnæus, from its being frequently observed in the houses of persons suffering from intermittent fevers; and it certainly is a remarkable fact that, during the summer when the cholera visited England, these flies appeared in such multitudes, that even the lamp-posts were often covered with them, in the vicinity of London. If such occurrences be not altogether accidental, and merely extraordinary coincidences, the only solution I can give is, that the state of the atmosphere which superinduces certain diseases, is at the same time congenial to the metamorphoses of certain flies. During the last summer a genus of flies called Chlorops, whose larvæ are very injurious to the Wheat and Barley-crops, appeared in vast numbers, and one of the species in such swarms at the end of September in a house that had been visited by scarlet fever the preceding summer, that the ceilings were literally covered with these little flies; it was stated "that you could scarcely place your hand where they were not: small crowds of the house-fly also hung about the window-frames." In this instance the ceilings had been whitewashed, the glare of which had probably attracted the flies, and the windows being almost constantly open, they had free ingress. Such was the case in October, when I observed the same species of fly in multitudes in an unoccupied house; indeed, a cross-light, or even a mirror opposite to a window, will often attract insects, especially the Diptera, or two-winged flies, to a great extent.

About the end of July, 1841, I received a considerable number of the larvæ of Dilophus febrilis, that had been detected in a Vine-border amongst the horse-muck; they are a quarter of an inch long, shagreened, of a snuff colour, or ochreous brown; they are slightly convex, wrinkled, and destitute of feet; the head is much narrower than the body, very glossy, and of a chestnut colour; ten of the abdominal segments are wrinkled, with a spiracle on each side, excepting the second and third; the penultimate segment is rounded with four teeth, and the anal one has four similar teeth, with two large spiracles near the base: fig. 1, magnified—2, the natural size.

These larvæ changed to pupæ, in the earth, in the beginning of August; they were white with a yellowish tinge; the thoracic portion was very gibbous on the back; the short antennæ were visible through the skin, and the head was furnished with two short thick points, like many of the Papilionidæ, or White-Cabbage butterflies, &c.; the abdominal segments were slender, the edges somewhat projecting, the apical one was tuberculated, and the tip furnished with two acute teeth (fig. 3, magnified; 4, the natural size). On the 21st of the same month they produced perfect flies.

The *male* of D. febrilis is intensely black, shining, and hairy; the head is hemispherical and covered with large eyes, densely pubescent and of a reddish-brown colour, with three minute ocelli, forming an elevated triangle near the base. The mouth is furnished with a broad lip and two incurved palpi; the antennæ are very short, stout, cylindric, and composed of eleven perfoliate pubescent joints; the thorax is oval and gibbous, with two transverse rows of minute teeth before; the scutel is short and broad; the abdomen is rather narrower, and eight-jointed; the apex clavate; the wings are incumbent in repose, iridescent, perfectly transparent and white, excepting the costa, which is slightly tinged with brown; the costal nervures are piceous, the others are very faintly traced; a radial nervure, uniting with the costal one at the middle, forms a brown spot at the extremity; the halteres are terminated by a large compressed brown club; the legs are long; the anterior thighs are the thickest, and their tibiæ the shortest, the apex being surrounded by a toothed coronet; there are several short spines also on the outside; the tarsi are slender and five-jointed, terminated by claws and pulvilli (fig. 5). The *female* is very different: the head is much smaller; the eyes are small, oval, and not meeting on the crown; the abdomen is brownish, ovate, narrowed at the base, and the tip is furnished with two little styles; the wings are much longer and larger, entirely brown, the costa being

the darkest, with a stigmatic spot; all the nervures are pilcbous, and the anterior thighs are very much inflated (fig. 6; the cross lines show the natural sizes of the sexes). These insects, like the Bibios, fly heavily, with their hinder legs hanging down; and, after sunset, rest sluggishly on herbage and bushes. I have found them in abundance towards the end of May, as well as in August; from which it may be inferred that there are two broods in a year, or else a succession of them.

Towards the end of March, 1840, a considerable quantity of similar larvæ were found under a pot in a Grape-house, where a fungus had been growing; some of them were more than a quarter of an inch long; they had spines on the thoracic segments, and one on each side of the folds in the following. I am rather disposed, however, to think they were the larvæ of the B. marci at an earlier stage of growth. A correspondent also transmitted some larvæ last August, which were darker, equally long, but narrower in proportion, and he informed me they were found in a flower-pot containing a Pelargonium, which had been watered frequently with water saturated with sheep-droppings. The earth in the pot, as well as that in the Vine-border, was perforated by the larvæ in all directions, but the Pelargonium had not suffered in health. There can be little doubt, however, that they are prejudicial to the growth of plants, but their economy requires farther investigation before the extent of mischief can be ascertained. So little is known of such matters, that I believe figures of the larva and pupa of Dilophus, and its history, were never before published. —*Ruricola.*

ROSE GARDEN.

In the list of Roses inserted in the *Gardeners' Chronicle* on the 14th, one or two errors have crept in. Billiard, Conque de Venus, &c., to Ariel, colour intensely bright, &c. This, from colour bright, wood healthy, and growth free, was intended to apply to Billiard alone, though the latter qualities suit the others also. Again, Brennus was not intended to participate in the qualities and habits of Mordaunt de Launay, Aimée Vibert, and Conque de Venus. Free in flower, colour rosy lilac, applies to Noisette Bougainville only. Vigorous in growth, colour brilliant white, applies to Madame Hardy only. In the *Chronicle* of last week the observations following Celestial were intended to apply to the above, and not to the Cerise.—*A. H. B.*

Home Correspondence.

Lisianthus Russellianus.—As this beautiful stove-plant is seldom grown to anything like perfection, I beg to mention the mode of culture by which I have grown it to 2½ feet in height and 1½ in diameter. About the middle of January the seeds were sown in finely-sifted leaf-mould, and covered slightly over with white sand. The seed-pot was placed in a moderately warm situation, and little water was given until the month of March, when the pot was placed in a brisk bottom-heat, and watered more liberally. The seeds readily germinated, and by the month of May the plants were potted off. The soil used was a mixture of two parts peat and loam, one of three year old cow-dung, and one of leaf-mould, with a proportionable quantity of white sand. These were all well mixed together; the pots were plunged in a Melon-bed, where the bottom-heat was about 85°. During summer the plants were regularly shifted, as they filled the pots with roots, and the shoots were frequently pinched back to cause them to throw out laterals. The roots were kept very moist, and the plants were well watered over-head every night; frequent waterings of liquid manure were given, which were of much advantage to them. By the month of September they were nice bushy plants, about 8 ins. in height; they were then removed into the stove, where they were placed in a dry situation, and where they enjoyed plenty of light. During winter great care was taken not to allow any water to fall on their leaves, and when it was given to their roots it was never allowed to touch the stem, but was applied round the sides of the pot, no more being given than what was necessary to keep the plants from flagging. Pieces of glass were placed below the lower leaves, to prevent the latter from being injured by moisture arising from the mould in the pot, for no plant with which I am acquainted is more impatient of damp during winter than this is. As spring approached they began to grow, and were shifted into large pots; the shoots were all properly staked out at the same time, pinching back the strongest; the plants were again plunged in a hotbed as before; their roots, as formerly, were kept very moist, and liquid manure was used frequently. Under this treatment they did well, and by the beginning of July were covered with a profusion of bloom, which fully repaid my attention. If, after the plants have done blooming, the old roots are partially reduced, repotted in smaller pots, and treated as young plants, they will form handsome specimens in the third year.—*A. S., Edina.*

Naturalist's Pocket Almanack.—I fully concur in the opinion of "The Naturalist's Pocket Almanack, for 1845," expressed in the *Chronicle* for the last two weeks; I cannot conceive upon what principle the Editor introduces many of his new names for insects? The two, amongst several, to which I would particularly direct attention, are Stŏrŏpēs and Tĕphrosia. Now, every person at all acquainted with the nomenclature of insects must be aware that (in England, at least, *vide* Curtis, Stephens, Westwood's Classification, &c.) Steropus is the appellation of a group of predaceous beetles, and although the *u* has, unfortunately, been substituted for *e* by the founder of the genus (Megerle), yet I do not conceive that to be a sufficient reason for adopting it as a generic title in another order of insects. Again, the name is a bad one to have given to a butterfly; for, instead of being dark and one-eyed, as we might fancy the recipient of such a title should be, one species at least is a pretty chequered insect, having, in common with its congeners, a peculiar jerking flight, and might well have received an appellation after some more airy creature than a cyclops. Not so the beetle, which has a fine glossy black or dark-brown coat, and ever delights in dark holes, whence it only emerges to seek for prey. With respect to Tephrosia, although it is a happier name for the insects which the Editor of the "Naturalist's Almanack" arranges under it, than Steropes is, yet it must be remembered that Tephrosia has long been used by botanists to designate a genus of plants included in the Natural Order, Leguminosæ. If, then, the nomenclature of the various branches of Natural History is to be altered after this fashion, I would ask, How is the student ever to find the particular object for which he is searching? In fact, in one instance he would look for a butterfly and find a beetle described; and in the other he would seek for a moth, and the description would answer to a plant.—*Stura, Canterbury.*

Autumn Planting of Potatoes.—In addition to the evidence already before the public on the safety and propriety of autumnal planting with regard to the Potato, I may mention that the practice has been followed for two years, with beneficial results, by some of the farmers in Fifeshire. The plants have endured the winter, come up vigorously, and produced an excellent crop. Nor may the period of planting be confined solely to the autumn months; it is probable that any open weather during winter will be equally suitable for the operation, as the following example may testify:—On the 27th of January last, a portion of a field was planted by J. Williamson, Esq., of Clunie, Perthshire, with whole Potatoes, in a rather poor soil, in a hilly situation; the stem came up vigorously at the usual period, and the plants yielded, at the time of digging, an excellent crop of fine large tubers. Those, therefore, who have not tested the experiment of autumnal planting, may still, during any interval of fine weather, plant a portion of ground for a trial.—*Vidimus.*

Birch Coppice.—The chief cause of Birch-stools not shooting when their main stem or stems have been cut, may be traced to the neglect of properly cutting, or heading down the young trees in the second or third year after they have been planted. When the early heading of the young plants has been neglected, and the trees have attained to 10 or 12 years' growth, there must be always a good deal of uncertainty with respect to their shooting again. From experience I have found that, when the stems have been cut in spring, they have [illegible] fresh shoots. To my cost, I was first advised to try the contrary plan of [illegible] fore Christmas, in order to prevent the stems, as it was said, from being weakened by bleeding. I was first led to alter the time of cutting from noticing the vigorous shoots from a few Birch stems which had been accidentally cut nearly as late as May. After much thought the bleeding of the stems seems to me to be a favourable symptom, as indicating the liquefaction, and flux and reflux of the sap, which is absolutely necessary for the formation, or at least the bringing into operation, of fresh buds. I have noticed in the stems cut before Christmas, that no bleeding has taken place, and that the fibres of the wood were filled with a hard resinous deposit of concreted sap. Whether this theory be correct or not, I leave to be proved by the observation of others; yet, in favour of it, I am able to show several single overgrown Birch stems, which were cut as late as March last year, and which bled most profusely, but which have also sent forth an abundance of strong vigorous shoots, and promise to become as good stools as I could wish.—*A. Forester, Romney.*——I have also suffered from young Birch-trees dying on being cut down; and I have tried the effect of cutting them at different seasons of the year, with but partial success. I have also covered the top of the stem, when cut, with a small turf, as recommended by old woodsmen. This fact, however, I have noticed after repeated trials, viz., that if Birch is cut for the *first* time after planting, *before* the bark assumes the white appearance it takes a few years after planting, and which happens at earlier or later periods, according to the soil &c., it seldom suffers from the cutting. The same may be remarked of Coppice-stools. It would be very useful if planters would communicate the results of their experience on the subject of cutting Birch in general.—*F. Berks.*

Mildness of the Season in Ireland.—I have a Jargonelle Pear-tree which blossomed late in October, and from which I inclose a Pear that set from one of three blossoms: it increased in size, and was evidently still trying to come to perfection, when I cut it.—*J. B. Warren, Warren's Grove, County Cork.*

Liquid Manure.—I have tried, and seen tried, several articles under the above name, with varied success, and I have seen such fearful havoc to arise from their use that I have now given them up altogether, and have substituted a manure which is within everybody's reach, and which has benefited every plant to which I have applied it. My manure is soot, dissolved or rather mixed with rain-water, in the proportion of one tablespoonful of soot to a quart of water for plants in pots, but for Asparagus, Peas, &c., I use 6 quarts of soot to a hogshead of water. It must never be applied to plants in a state of rest. It succeeds admirably with bulbs. By its means, and without artificial heat of any kind, I have now (Dec. 4th) a Van Thol Tulip in flower on my table, and I hope to have Hyacinths in bloom by Christmas day or shortly after.—*X. X.*

To Clear Frames of Insects, &c.—I have no greenhouse, but I have put up two shelves (back and front) in a two-light frame. About the middle of October I had everything taken out of the frame, which was then well swept with a birch broom—every crevice in the wood was stopped with putty, and any holes in the bricks, with mortar. I then had sufficient quick-lime put into water to form a mixture, about as thick as batter; to that I added a quarter of a pound of powdered brimstone, and while hot had every part, shelves, both upper and under sides, supports, and all covered with the wash as thickly as it could be put on. When dry, this was repeated, and as yet I have scarcely seen an insect, although the pots stand so thickly that it would be difficult to place another among them. From the commencement of the present frost, I have uncovered but once a day, and that is about 11 in the forenoon. I always burn a rushlight, and the piece that remains in the water in the morning is dried. I then put it into a lanthorn, light it, place it in the bottom and middle of my frame, and then close up by putting mats next the glass so as to hang down all around, and over them a covering of asphalte. With this trifling care and protection, I have now (Dec. 10th) Pelargoniums, Cinerarias, Fuchsias, Cacti, Primulas, Roses, and various other tender plants, looking as well and healthy as I can desire. I forgot to state that the ground is well drained, and that I put one fourth of ashes in the bottom. I never water a plant in the frame, but take it out when it requires water, and afterwards restore it to its place. —*X. X.* [Very good.]

Lime Putty.—In answer to "A. B. J." I beg to state that lime-putty is lime ground up with raw linseed-oil, and made to the same consistency as that of common putty.—*Junius.*

Mode of Destroying Tomtits.—Take mutton-suet, and grate it with a large kitchen grater, such as cooks use; make balls of the grated suet, and put a ball of it into a fine net; hang this on trees in the garden, and Mr. Tom will soon invite all his relations and friends, and the net will soon want another charge. Grate suet again, as before; and to 1 oz. of suet add 1 scruple of fine powder of nux vomica; mix this well with the suet, and put it into the net, placing the latter in the same situation as before; Tom will soon give the signal to his companions again, but he will not repeat this many times. This plan will possibly answer better than "W. K.'s" cage. I may remark, in passing, that "W. K.'s" redbreast, of which he speaks so much, is as great a thief as can be in a garden, and deserves to be killed as well as Tom.—*Scrutator.*

Modern Flower-gardens.—If we want to gain a correct knowledge of any object, we must not only see it, but look attentively at it; and so also, if we would arrive at [illegible] of the principles of modern flower-correct notions of [illegible] gardening, we must exercise our understanding in regard to our object, and have a mental power of carrying the image of the object along with us, before anything like agreeable combinations can be produced. Now, I have observed that a square figure, divided into four triangles, and planted with plants of one height, but of two opposite colours, represents harmony and diversity; and when these are so arranged that the one side of the figure reflects the other, an agreeable effect is produced on the eye, indicating its healthy state, and at the same time illustrating the whole theory of colours. It is a principle of perspective, that a large figure is more imperfectly seen near a person than a small one, in consequence of the rays of light reflected from the large figure passing by the eye; and whether it is a square figure divided as above, or one differently arranged, so as it comes within the intersectional angle thus formed by the eye, the principle of planting in both cases will be the same.—*C.*

Onions.—I have this year an excellent crop of Onions, both in regard to weight and size; they were supplied with large quantities of manure out of the tanks in its original state. I should, however, mention that a good deal of pure water also runs into each of the tanks.—*Omega.*

Scorching Effects of the Sun.—If our hands or our faces are dipped either in cold or tepid water and exposed to the full sunshine till quite dry, they become stiff, and feel for a short time as if in a case of gum. Take a laundress's iron, or a poker made hot, dip a piece of linen in water or your hand, and take hold of the poker; do not remove the hand till either it or the linen is dry, and then if the hand do not exhibit an injured epidermis, I will believe that leaves may not be injured under similar inflictions. Again, it is admitted that leaves of plants are furnished with pores, similar to the breathing-pores of some insects, through which they receive the nourishment afforded by the atmosphere, and give off that which is superfluous, as we do by our lungs. In full sunshine they may be expiring or sweating; and I am inclined to believe that that man "burkes" his plants who would water them under such circumstances; for, these pores being shut up when wet, may have their expansive muscles injured by the sun and water, and thus the superfluous water or evaporating part, or perspiration, is checked; the system of the leaf receives a shock similar to that which the human frame would experience from being placed in a draught; colds, fevers, erysipelas follow from a sudden transition either to one extreme or the other, the body having an unnatural charge put upon it. The active presence of the rays of the sun makes a difference in the effect of the application of water. A large stone slab is laid outside of my drawing-room window, the aspect is

east, inclining to north; on this I have Fuchsias, &c., in pots; they are, in very warm weather, invariably watered as soon as the sun is fairly off them, and this is generally repeated once or twice afterwards during the day, and more healthy plants cannot be seen anywhere. The analogy between watering in the full sunshine, and a sunshiny shower, I imagine is widely different; because Cabbages, Beans, Lupines, and many flowers, which droop from the heat of the sun, hold up their heads before the shower—a sure indication of rapidly approaching rain. What can effect this but a susceptibility in the plants greater than that which the frame of man possesses, and a restringing of the flaccid muscles of the plants to open the mouths or pores for the grateful drops? The rays of the sun being broken by the glass of forcing-houses, a greater moisture does or should exist in the atmosphere of that climate than in the air; therefore, the application of water at any time of the day must cause a less shock to the plants than it would out of the house.—*A. W.*

Rats.—A few weeks ago a vast number of rats were driven into the Thames by the sudden damming up of a sewer. How very easily might London be cleared of these vermin by placing sluices in the sewers and drains, and once a month, on a given day, stop them all up for a certain number of hours, and then let the water, &c. off into the river! No rats could harbour and breed in them then. Again, if in the country, 1*d.* a head was given for every rat, they would soon be annihilated.—*D.*

On Budding the Vine.—About the first week in March I perform the operation, or as soon as I perceive the sap begin to rise. I cut from a Victoria Grape an eye about three inches in length, having attached as much wood as I could possibly get with it; at each end of the eye I cut off about a quarter of an inch of the upper bark, making the ends quite thin. I next measure off the exact length of the bud on the base of the Vine intended to be budded, and make a nick slanting upward at the upper part, and another slanting downward at the bottom. I then take the piece neatly out, so that the bud may fit nicely in, and by making the nick as stated above, each end of the bud is covered by the bark of the shoot. I bind the buds firmly round with matting, and clay it, taking care, however, that the clay does not cover the eye of the bud. I then tie it round with moss, and keep it constantly damp; and as the sap rises in the Vine the bud begins to swell. When the Vine commences to push out young shoots, take the top ones off, in order to throw a little more sap into the bud, and as you perceive it getting stronger, take off more young shoots, and so continue until you have taken off all the young shoots. Budding can only be performed where the long-rod system is practised, as in that case you have the power of confining the sap to the bud, which will grow vigorously. As soon as you perceive this, cut the Vine down to the bud. Budding has the advantage over grafting, by not leaving an unsightly appearance where the bud was inserted. A bud likewise grows more luxuriantly. I have seen a bud [illegible] a shoot fully 30 feet in length, with a beautiful bunch of Grapes at the base in the first season; whereas a friend of mine bought a plant and grew it for two years before he obtained fruit from it; and even then his Vine was not equal to the bud. I have budded many Vines in the same manner, and have always found them answer the end. I always allow the matting to remain on until about the month of September, when I take it off, and I have always found the bud perfectly united; and without minutely examining the plant the work is imperceptible. —*E. L. S.*

Rabbits.—When I lived at Seaton Sluice, my companions and I used to go at nights with a dark lantern on Hartly Links, and catch rabbits with sea ferrets, as we called them. We got large crabs (commonly called dog crabs) from off the rocks; we stuck a lighted candle about one inch long on the crab's back, and sent them into the holes, before which we placed a net. Before the crab got far into the hole, the rabbits came tappy lappy into the nets. In this way we caught numbers of them in a short time.—*J. P.*

Plants for Hybridising.—Among other plants I would recommend the trial of hybridising the Daphne Laureola, and the Mezereum, so as to obtain a Laureola with red or white flowers, and to clothe the Mezereum with green leaves. There is a white Buttercup, which if hybridised with other kinds of Ranunculus, may give us a race of entirely new flowers.—*D.*

Strawberries.—As it is of great importance, in growing Strawberries in the open air, to make them produce fine fruit as early as possible, without loss by frogs or slugs, &c., which loss is generally very great, the following plan may be found useful:—Fix on each side of the row of Strawberries, just before they come into blossom, feather-edged boards at an angle of 50° or 55°. This may be effected by nailing two narrow slips of wood to each board, and pushing them into the ground. The boards should be painted black. This plan makes two or three weeks' difference in the ripening of the fruit; but glass, or an oiled-paper frame, being placed on the top, makes a greater difference still, and prevents any of the fruit from being trod upon, or eaten by vermin. This plan, at first sight, may appear to be an expensive one, but it is not so; any old boards will answer the purpose. I have bought old feather-edged boards at ½*d.* per foot; and, as they are only used in summer, they last for many years. The expense is saved in the first year; for the wood, although painted on each side with a coat of invisible-green, costs only about 1¼*d.* the foot; while the increase of fruit in quantity, as well as in quality, quite compensates for the outlay. In conclusion I may observe, that watering with strong liquid manure two or three times in the month of February, and frequent waterings during bearing time with pond-water, are, I have found, very beneficial.—*G. L. Smartt, Enfield.*

Dry-rot in Timber.—I have had a great deal to do with this, and I have tried many remedies, but have found none to answer except the following, which I tried about four years ago. I took 3 lbs. of corrosive sublimate, and put it into a large glazed earthen pot; to this I put about 4 gallons of water, and when it was well dissolved I took a large painter's brush, and washed the timber and walls with the water, and no symptoms of rot have made their appearance since.—*Scrutator.*

Productive Variety of Apple.—The Rymer Apple, Caldwell, or Cordwall, as it appears to be called near Nottingham, proves a most productive and valuable sort. The following note accompanied a specimen of the fruit:—The tree will cover 100 yards; and 240 pecks have been gathered from one tree and sold for 14*l.* 15*s.* 8½*d.*—*S. R. P. Shilton, Nottingham.*

Pruning Forest Trees.—Much has been said of late in the *Chronicle* on thinning and pruning forest-trees; and much difference of opinion seems to exist on the subject. A good deal, nevertheless, of what has been written both for and against pruning is, in my opinion, calculated to mislead those who have not sufficient knowledge and experience to judge for themselves. "Prune not at all if you can help it," is a good maxim when properly understood and applied; but no practical man can deny that pruning is often necessary, and when it is so, must not be neglected. An unskilful pruner may overdo it, but abuse of a system is no argument against the utility of the operation. Mr. Thompson of Whitehaven, in his article (p. 795) makes some excellent remarks on the subject, in which I entirely concur; but the method he recommends, where plantations are extensive, would require too much labour and expense to be practicable. Admitting the fact, that the greater the quantity of foliage in a tree, the greater is the quantity of timber produced, it does not follow that the greatest quantity of valuable timber is produced: this, I am persuaded, can only be obtained by judicious thinning and pruning. The exact age at which to begin thinning and pruning a plantation must depend, in a great measure, upon the kind of tree, upon the situation, upon the closeness at which the trees are planted, and upon the rapidity of their growth. These things must be left to the judgment of the person having the management of them. The plantations of which I have now the charge afford good examples of the effects of thinning and pruning, and of the neglect of these two assistants of nature. These plantations are of different dates, the oldest being about 40 or 45 years of age, and the youngest about 20. For many years, according to what I have been told, the plantations were regarded, at any rate were treated, more as harbours for game than as [illegible] of profit. They were left [illegible] very much to nature. In course of time, however, it was discovered by the proprietor that he had run the risk of sacrificing all hopes of profit, without securing even permanent shelter for game. The trees were drawn up into an impenetrable mass, leaving the earth bare; the deciduous trees twisted themselves like whips through the branches of the Firs, originally intended as their nurses, in hope of catching a breath of air, or a gleam of light; and the Firs themselves grew indeed at top, but with all their lower branches rotting off. The mistake was happily discovered in time to save the later-planted woods; and for the last 10 years and more a judicious system of thinning and pruning has produced as fine a crop of trees (of young Oaks chiefly) as is rarely to be met with, forming a striking contrast to their elder brethren, who are still suffering from want of a timely and wholesome application of the knife. The method pursued here is as follows:—When a young plantation has arrived at such an age as no longer to require the Firs as nurses, the latter are thinned out, leaving them only scattered about in spots suited for them; the deciduous trees, which are chiefly Oak, are then moderately thinned wherever the branches are observed to interfere with one another, and, where it is required, a few of the under branches are cut off close to the stem, taking care, however, always to leave a sufficient proportion of top. The tops are carefully looked over in order to remove all shoots that are likely to rival the leader, and such branches are fore-shortened as appear likely to affect the proper balance of the top. In a few years the same operation is repeated, and so on until the trees are about 20 or 25 feet in height, when I consider pruning not only unnecessary but injurious, excepting in particular cases.—*G. S. H.*

Hereman's Vegetable Dilutium.—This destroys the mealy-bug, and may be used with safety for cleaning many plants, if Mr. Hereman's directions are strictly attended to. There are, however, some plants that, although the dilution is carefully administered to them, are apt to be injured by it. I have observed, in applying it for the destruction of mealy-bug on Mammillaria gracilis, that wherever the liquid touched the plant, that part of it perished; therefore, those who adopt this method of destroying insects should be cautious how they perform the operation.—*D.*

The Wren's Nest.—At p. 910 of last year's *Chronicle* I made some observations on the cock wren's nest, which have been again fully borne out this year: the same two birds have continued together as I have described, until their death, which happened yesterday morning (Dec. 14.) I found one of them dead on the ground, near the wall of the cottage where the nest was. This led me immediately to examine the nest, and there I also found the other (the cock) dead in the nest; no doubt their death was occasioned by hunger and cold, the frost being very severe here for the last fourteen days; indeed, surpassing any we have had for some years at this season. These, however, are not the only birds which have suffered from the severity of the weather. I have to-day (Dec. 15) met with the P. pelagica dead at this place, which is seven miles from the sea; it was 6 inches in length, and weighed 7½ pennyweights. This bird inhabits most seas. It is seldom seen even near the shore. It braves the utmost fury of the storms; it is sometimes seen skimming with incredible velocity along the hollows of the waves, and sometimes on the summits, and if seen hovering around the sterns of vessels is a sure presage to seamen of the approach of severe weather. —*M. Saul, Fort Green Cottage, Lancashire.*

Stephenson's Boiler.—I was induced to purchase one of Stephenson and Co.'s improved Conical Boilers last year, for the purpose of heating my Grapery, in which I keep, during the winter, my Pelargoniums and a few other plants. I used for fuel coals and cinders, but I soon found, that although the heat in the cast-iron pipes was quickly raised to the requisite temperature, the fire soon went out; in fact, it could not be left an hour without attendance. In consequence of this serious defect, I called upon the manufacturer, who assured me that if I changed the fuel, and used coke broken into small pieces, I might leave the fire for 12 hours without attendance. I stipulated for eight hours, and they agreed that if the fire did not continue burning unattended for that period, they should consider their boiler a failure. I have since adopted the coke, and certainly find it answer much better than the coals or cinders; still I do not consider that the fire can be safely left even now for more than two hours; and, notwithstanding my man has remained up very late during the present frost, some of my plants have suffered. Perhaps some of the readers of the *Chronicle* who may chance to have one of these boilers, will have the kindness to inform me what they think of them; and whether my want of success hitherto arises from defective management.—*Thomas Canning, Elsenham Vicarage, Bishops' Stortford, Herts.*

Destruction of small Birds.—I perceive in the *Chronicle* of last week, that the "Laird o' Cockpen" seems almost to condemn the poor sparrow, whose cause I have often advocated, on account of its mischievous acts in destroying the buds of his Gooseberry-bushes. I certainly admit that it is difficult to excuse the acts generally of this mischievous little fellow amongst the Gooseberry-bushes, Lettuce-beds, &c., and in tapping the young Peas on their first appearance above ground. It is true such depredations are very grievous; but let us closely pursue his actions during the spring and summer months amongst the various fruit-trees, and we shall find his services in thinning the ranks of numerous Caterpillars, so destructive to both blossom and fruit, as well as [illegible] in destroying various species of aphis, moths, butterflies, beetles, &c., to more than counterbalance the evils we have admitted. Bradley has calculated that a pair of sparrows having young to maintain, will destroy 3360 caterpillars in a week! And indeed, from my own general observation, I am of opinion that were it not for the sparrow and other birds destroying the caterpillars in seasons when bloom is scanty, little or no fruit would be the result. I think, however, the crimes of this little culprit may be a good deal prevented by frequently dusting the bushes well with quick-lime just after rain, that the dust may better adhere to the plant; and so with Peas, &c. I may here repeat what I have before stated in other publications, viz., never to destroy birds indiscriminately, but to notice their usefulness. Among the insectivorous birds I may mention the blue-cap, the fly-catcher, the spink, the thrush, the blackbird, the rook, &c.—*Joshua Major, Knosthorpe.*

Reviews.

Geology — Introductory, Descriptive, and Practical. By David Thomas Ansted, M.A., F.R.S. 2 vols. Van Voorst. 1844.

Geology, through the large accumulation of facts by later observers, has, within the last twenty years, assumed quite a new character. Its first cultivators had a large field before them, in which there existed only a few well-attested facts, and with these scanty materials did they build up the structure of their science. It is not to be wondered at that generalisations too large for their facts, and assumptions, that would not bear the rigid application of the principles of other sciences, occupied a prominent place in their speculations. Geology requires, perhaps, more knowledge of correlative sciences than any one we could name, and yet it was not uncommon to find that those who cultivated it were ignorant of the first principles of every department of science it embraced. Such was its position till very recently, when the vigorous minds and active hands of such men as Smith, Lyell, Phillips, Sedgwick, and others, came to its rescue, and geology and geologists are no longer a jest amongst the sister sciences. At the same time, we have a deep conviction that some of the most ardent cultivators of geology have much need to bring their minds in subjection to the admitted principles of the sciences of chemistry, botany, zoology, and comparative anatomy. The want of this knowledge is very evident in many of the works introductory to geology. We are glad, however, to find that Professor Ansted has been induced to publish these volumes, containing the subject-matter of his admirable lectures, and we have no hesitation in stating, after a careful examination of the work, that in regard to a knowledge of the relation of other sciences to geology, it is in advance of books hitherto written on the subject. The work is distinguished from others by its

being confined in the first place rather to the statement of the facts of geology, as at present known, than to the development of the causes which may have acted in producing the present relations of the facts stated; and in the second place, by the practical application of the principles of the science. Of the style and manner in which the subject is treated we give the following extract from the short introduction descriptive of the causes now in action affecting geological phenomena.

"Of the many constantly recurring phenomena, which owing to their perfect and undeviating regularity attract but little notice from the casual observer, there is none perhaps more remarkable than the quantity of solid matter held for a time in mechanical suspension in the water of rivers, and brought down to be deposited at the mouth of the stream, or spread over the bed of the ocean. The vast amount of mud thus conveyed by running water is occasionally seen in the extensive deltas, or tracts of swampy land, at the mouths of great rivers, such as the Rhine, the Po, the Nile, the Ganges, &c.; in each of which cases the river divides into so many channels before reaching the sea, that its actual character and apparent magnitude is completely lost.

"The origin of these vast deposits of rich alluvial soil must be sought for entirely in mud brought from the high lands or the plains through which the river passes, and held in suspension so long as the water is in rapid motion, but which sinks to the bottom when the current is checked. To obtain some notion of the actual quantity of solid matter thus continually brought down from the high land to the sea, an experiment was made some years ago by Mr. Leonard Horner,* on the water of the Rhine, the calculations founded on which possess considerable interest. Mr. Horner found that in the month of August, when the river was unusually low, one cubic foot of water taken fairly from near the middle of the river, near Bonn, supplied rather more than 21 grains of solid matter, and that in the month of November, when the water was turbid, about 35 grains of residuum were obtained. Now, taking the average of these two observations, and considering the Rhine at Bonn to be 1200 feet wide, to have a mean depth of 15 feet, and to run with a mean velocity of 2½ miles per hour, it appears that nearly 400 tons of solid matter would pass down the stream per hour; and that in the course of one year, between seven and eight thousand millions of tons would be carried along, the greater part of which must be deposited in Holland before reaching the sea, in consequence of the slow and meandering course of the river through that flat alluvial country. In the course of 2000 years, the Rhine may thus have brought down enough material to form a stratum one yard thick, extending over an area more than 36 miles square.

"But the delta of the Ganges far surpasses in magnitude that of any European river; and is, on the whole, perhaps, the most extensive and remarkable of all those at present forming of which we have any accurate data. The head of this gigantic delta commences at a distance of 220 miles in a direct line from the sea, and the base of it is 200 miles in length; the whole triangular space occupied, comprising upwards of 20,000 square miles, every part of which has been formed by deposition from the river and its tributaries.

"The quantity of mud and sand carried by the Ganges into the Bay of Bengal is, however, notwithstanding the vast deposit which previously takes place, still so great, that during the rainy season, when the stream is turbid, the sea does not recover its transparency even at a distance of 60 miles from the coast; and the quantity of mud held in mechanical suspension is so great, that a glass of water taken out of the river when at its height, is said to yield one part in four of mud. Calculating from the dimensions of the river and the rate of the current, Major Rennel has shown, that during the flood season the weight of the mud thus brought down daily and deposited either within the limits of the present delta, or at the mouths of the different branches, must be as much as 450 millions of tons—a quantity which is, perhaps, more readily understood by expressing it as equal to about 74 times the weight of the Great Pyramid of Egypt, supposing that to be a solid mass of granite."

The introductory remarks on the nature of fossils and their value in geology are very important. We would also point out the chapter on the fossils of the Palæozoic period to those geologists and botanists, who are so fond of the theory of a gradually more complicated development of animal and vegetable forms. From this chapter it will be seen that the theory which supposes the simplest animals and plants to have been first created rests on a mere assumption. The second volume is mostly taken up by the practical application of the principles of geology to civil engineering, architecture, and agriculture. We deem this not only the most novel feature of the work, but also the most important. If Professor Ansted does not possess that intimate knowledge of these branches of art, which is looked for in their professors, and which would render his opinions conclusive, he has at least opened up an important subject for inquiry, upon scientific principles. As an example, we give the following extract from the chapters on Agricultural Geology:—

"With regard to the relative value of different geological formations in agriculture, it will be evident, from what has just been stated, that no general rules can be laid down; and that, as it is rather the mineral and physical character than the geological age, the determination of which is important, the geologist can only bring his knowledge to bear in any given instance when he has informed himself of the actual structure of the district. In our own country, the older rocks are frequently barren, in consequence of the absence of limestone; but where that is present, and there is a due admixture of silica, argil, and limestone, as in some of the Silurian districts, and some parts of the old red sandstone, a strong and excellent soil is obtained. The old red sandstone, both in Herefordshire, and elsewhere, where its texture is good, is often exceedingly productive.

"The soil which covers the strata of the carboniferous or newer Palæozoic period is rarely of great value for agricultural purposes, owing to the preponderance of crystalline limestone in a condition which resists decomposition, and the almost uniform absence of argillaceous beds, except in the upper part, and associated with the coal measures. In these latter beds, however, the presence of argil does not tend to render the land productive, so that the whole series of these rocks is poor and valueless so far as the surface is concerned. Fortunately their mineral treasures beneath the surface far more than make up for this deficiency. The culm measures of Devonshire do not form an exception to the general agricultural condition of the upper carboniferous beds in other parts of the British Islands.

"The magnesian limestone, overlying the coal measures, and covered up by the beds of the new red sandstone, is not uniformly valuable for cultivation; but some of the districts where it preponderates are remarkable for being the best and richest grazing districts in the north. The magnesian limestone, if burnt, and used on the soil, is, however, extremely injurious, remaining for a long time in the same state, and seriously checking all kinds of vegetation.

"The new red sandstone, although not so thick as many of the older beds, covers a very large tract of England, and is remarkable almost everywhere for its great fertility. It consists of sandstones and sands, for the most part of loose texture, and alternating with innumerable beds of marl; and these are most abundant in the upper portion, which is not unfrequently characterised by a strong marly loam. Hence it arises that the latter, being the stiffest and most clayey bed, is usually employed as arable land; while the remaining portions are admirably adapted for pasture, and are celebrated in some parts of the country for the excellence of the hay grown upon them.

"The lias, with its associated marlstone, varies from a cold, wet, and extremely tenacious blue clay, to a strong and valuable clayey loam, and its value in an agricultural sense depends on the proportion of limestone and marl associated with it. In the upper part, where the sands of the inferior oolite rest upon it, they are sometimes turned in, and mixed with advantage; but there is always in such case a want of drainage, and the soil remains cold. The principal part of this formation is in old pasture, and forms the dairy districts of Somerset, Warwick, Leicester, &c.

"The oolites (including the wealden) consist of so many alternations of calcareous beds with sand and clay, that they offer almost every variety of soil, and are throughout capable of the highest cultivation. Where the limestone is too prominent (which is sometimes the case), the clays are generally at hand to correct the evil; and the clays, if sometimes too stiff and tenacious, require only a thorough system of drainage to furnish the best and richest crops of Wheat that can be grown in our island. The great oolite is, perhaps, the bed least readily turned into cultivation, and this arises from the small quantity of carbon it retains upon its surface. The wealden beds, also, are apt to form into hard pasty masses, into which the roots of vegetables penetrate with difficulty.

"The beds of the cretaceous group vary much in agricultural value: the lower beds, those of the lower greensand, are often exceedingly rich and capable of the highest cultivation, and the upper chalk forms extensive downs, which are well known for their short sweet herbage, supporting large flocks of sheep. The lower beds of chalk are without flint, and are often mixed with alumina, which converts them into a rich and valuable marl; while the soil at the junction of this marl with the upper greensand is a very productive loam, making an excellent corn land."

We think this work a valuable contribution, not only to the science of geology, but also to the practical arts to which its principles may be applied. It is written in a clear and pleasing style, and cannot fail to interest whilst it instructs. It is abundantly illustrated with woodcuts, and is a worthy companion, in point of getting up, to the many excellent volumes published by the house of Van Voorst.

* Edin. Phil. Journ. for 1826—2, p. 103.

NOTICES OF NEW PLANTS WHICH ARE EITHER USEFUL OR ORNAMENTAL.

ANEMONE OBTUSILOBA. Dr. Govan's Anemone. (*Hardy Perennial.*) Ranunculaceæ. Polyandria Polygynia.—This pretty Indian Alpine herbaceous plant has been already noticed, under the name of A. Govaniana, which is what Dr. Wallich called it. It escaped my observation that Professor Royle had determined that species to be the same as A. obtusiloba of Don, which name must take precedence. It is nearly allied to A. narcissiflora, which is, however, readily distinguished by its short flower-stalks and deeply divided leaves. The native situation of the species is stated by Dr. Royle to be the Choor mountain of the Himalayas, at elevations of from 10,000 to 12,000 feet, flowering in May. In cultivation it proves to be a hardy little Alpine plant, growing about six inches high, and well suited for pots, or a rockwork where the situation is rather shaded and damp. It is easily increased from seeds, which should be sown early in spring, in a soil composed of sandy peat and leafmould, and a small portion of loam; afterwards, when the young plants are large enough, they should be potted singly in very small pots, and kept in a cold frame, with the back turned to the sun during the summer. Afterwards they may be treated in the ordinary way, but they will not flower before the second season. *June* and *July* are the blowing months. It was raised from seeds received by the Horticultural Society from the Honourable Court of Directors of the East India Company.—*Botanical Register.*

SALVIA STRICTIFLORA. Erect-flowering Sage. (*Half hardy Greenhouse Shrub.*) Labiatæ. Diandria Monogynia.—The genus Salvia is well known to consist of a vast number of species, many of which are as remarkable for their beauty and bright colours, as others are uninteresting in their general figure, and void of brilliancy in the hue of their flowers. The latter characters are more particularly the faults of the strictly herbaceous species, whilst the larger number of the shrubby and suffruticose kinds range under the former class. The subdivision of the genus to which this handsome plant belongs (Longidora) is almost entirely composed of shrubby species, distinguished by the tube of the corolla being two or three times longer than the calyx, and the upper lip usually extending to a somewhat greater length than the lower; and it is in this section that the majority of the most choice and charming species are enrolled. Although yet so little known in the country, we learn from the "Botanical Magazine" that specimens of S. stricticflora were flowered in England so long back as December, 1834. The same authority states that it was discovered by Mr. Cruikshanks between Yazo and Obrajillo, in the valley of Canta, in Peru; and subsequently collected by Mr. Matthews, at Cuesta, at Hummarilango and Parcochuco, Peru, where the natives distinguish it by the title of Socconcha. Being a plant of rapid growth, liable to extend its soft wooded branches to a great length, and bearing its upright racemes of vermilion blossoms at their extremity, the propriety and utility of occasionally pinching off the ends of the growing shoots, to produce increased bushiness and quantity of bloom, is self-evident. And for the same reason it should never be planted in a gross strong earth of an adhesive or retentive nature, as this would augment the natural propensity to undue exuberance. Equal quantities of sandy loam and peat, with a loose stratum beneath to carry away superabundant moisture, will be most consonant with the habit of the species. It should be placed in an airy part of a greenhouse or frame to stand the winter. Propagation is easily managed by preparing cuttings of the young wood in the usual way, and placing them in a gentle bottom heat. The upward direction of the tubular flowers has suggested the specific name.—*Paxton's Magazine of Botany.*

Garden Memoranda.

Royal Botanic Garden, Edinburgh.—In the Heath-house at this place are some splendid specimens of this beautiful tribe, and among them was one of Hyemalis, which measured 8½ feet in height, from the top to the surface of the earth in the tub, and fully 9 feet in diameter. From a careful calculation, by enumerating the flowers on several individual spikes, and multiplying the whole, I am satisfied that there could not be fewer than 120,000 blossoms on the plant! The tub in which it was growing measured 4 feet in width, and 3½ feet in depth. When we consider the short time that this hybrid has been in the country (about six years), those who know anything about the culture of the Heath will have no hesitation in pronouncing it to be one of the finest specimens of horticultural skill that has ever been produced, and which will still retain for Mr. M'Nab the palm in Heath-growing.—*A. S. Yester, Dec.* 21.

Miscellaneous.

Scotch Chemical Association.—Our letters inform us that this Association is prospering, as it ought to be. Professor Johnston has been invited to lecture in several parts of the country, and the knowledge and taste for Agricultural Chemistry are evidently spreading among the sharp-witted Scotch farmers.

Central America.—The following are some of the productions of the State of Costa Rica, in Central America, viz.:—The Sugar, wild and white cane, and that of the class called Brota, which spread out, forms strong planks more than half a yard in width, and 5 or 6 yards in length; Coffee (which, being properly plucked and dried, is exactly similar to that of Mocha); three sorts of Cacao or Chocolate, Indigo, Vanilla; three sorts of Maize, seven kinds of French Beans, Peas, Beans, Rice, Wheat, Musk, and Water-Melons. In a word, innumerable medicinal plants, and all the Cereal, so that Botany would find amongst us a vast field in which to range with unspeakable advantage to humanity and society in general; three sorts of Plantains, three of Cotton, Tobacco of many kinds; Timber, for mills and other works, which require hard woods, such as Quapinol, the Lignum-vitæ, the Wild Medlar tree, and the Oak; for houses and joiners' work, mahogany of the most excellent quality; the Casique, the Cocoa-nut tree, the Rouron, and the Cristobal; the Beech-tree, three sorts of Cedar, the Curagra (which, from very recent observation, is considered the best substitute for Cedar), the Chesnut, the Espavey (also called the Espavel, or Aguegue), and the Laurel. For house-props, not liable to rot in the earth, the Chirraca, the Tubus, the Bayuilla, the Guachapelin (a very strong wood), the Quisbrahacha, the Black Wood, the Comenegro, which is exactly the same as the Iron-tree, so celebrated in the East Indies, and other countries; finally, dye-woods, such as are called Brazil and Nicaragua, found on the coasts of the Pacific and Caribbean; the San Juan, of a beautiful yellow; Poro, from which is extracted a very bright yellow cane-colour; and, above all, the wild Annona reticulata, which has the particular property of its wood being perfectly white, but when cut or split, in a few minutes turns to a clear and brilliant red colour, which can be extracted, and which is quite durable; Balsam cavuna, or canune, Copaiba, and Tolu, and Cativo; the gums Copey, Resin, Copal, Arabic, Quitirri, Guapinol (an excellent perfume), incense, Chirraca, and that of the Chesnut-tree, the fruit of which contains much oil, and has the property of becoming hard, and of which candles are made, very like yellow wax, burning with a good clear and steady light, without giving out much carbon; this seed and substance being worked and purified, makes candles as fine as those of white wax.

CALENDAR OF OPERATIONS

For the ensuing Week.

I.—HOTHOUSE, CONSERVATORIES, &c.

Orchidaceæ.—In reference to the shy blooming kinds, the most essential part of their management is to compel them to

flower gradually. Every day's delay after this will make the flowers smaller and less beautiful, and more susceptible of being destroyed by changes of temperature or moisture. As soon as the flowers are gathered, the plants should be removed to the open ground, and there remain until the end of November or the middle of February, when they should be potted for the last time. The atmosphere should not be allowed to get too dry, and the leaves must be syringed frequently, and the plants shaded from bright sunshine, while the material about the roots must not be allowed to get dry. Early in March, however, will be apt to grow at this stage, particularly in the first season; these must be kept in a cool temperature, 50° in the driest end of the house; 70° to 75° during the fine temperature for April. Every bud now will be encouraged, and the success of the plan depends in some measure upon the season of the year when the buds can be kept in this state. As soon as the roots have filled the pots they should be shifted into pots about two inches larger, and pieces of charcoal and bits of bone mixed with the soil. The plants will require to be plunged over the rim in tan, above hot-water tanks, and have required nothing to be done to them since, except sprinkling the foliage occasionally with the syringe or watering pot; the latter only in very hot weather. The plants have grown amazingly, throwing up leaves of a remarkable breadth and firmness of texture, while the lumps of earth are completely matted with fibres. Some of the plants are now in flower, while others appear as if they would grow for some time yet. I intend to have a pit treated in the same way next year, but will use the dust from the charcoal pits as a plunging material instead of tan. I have reason to think that charcoal dust used in this way acts in a beneficial manner on the plants, by impregnating the atmosphere with carbon. It is impossible to convey an adequate idea of the change produced in a few weeks on the foliage of a house of plants where this material had been used, every plant in the house, whether plunged, or placed on the shelves, assuming the most dark and healthy hue possible.

Borders.—The borders of the late Vines are showing no slightly look as soon as the frost will admit of any proper pruning on any top-dressing at this season, as the frost will be of more service to the border than manure. Top-dressing does more good in the growing season, as it flourishes the Vines and keeps the roots in a more uniform state of temperature and humidity. Let the roots of the Vines now forcing have every attention. The keeping of the roots warm is, perhaps, the most important point to be attended to, next to the avoidance of over-cropping.

Cool-houses.—The last few days have been very favourable to the Peach-trees now setting their fruit. Be careful to avoid too high a temperature at night, and take every opportunity of giving air till all the fruit is set, after which the temperature may be raised 5° or 6° by night and 7° or 7½° by day. Keep a very moist atmosphere, and thin out the young shoots, leaving always the top and bottom ones remaining on each of last year's shoots.

Cherry-house.—Be careful not to keep too high a temperature, particularly during this cold weather; 45° by night will be quite sufficient, until the buds are about expanding, when it may be raised to 50°. Air must be admitted during a portion of this day, to extinguish the bees after they are perceived to be crawling.

Stove-house.—Let a quantity of them be brought in, according to the demands likely to be made upon you. Place them on the shelf of a Peach-house or Vinery just beginning to be forced, as near the glass and ventilators as possible. It is better when practicable to force them in pits where the temperature can be regulated to suit them, as they require more air than either Vines or Peaches till the fruit is set.—*G. F.*

V.—HARDY FRUIT AND KITCHEN-GARDEN.

Pea and Bean.—As soon as the weather will permit, make another sowing of Prince Albert Pea and early Mazagan Bean on the brow of wide ridges, as previously recommended; and, lest the ground should afterwards be frozen hard so as to impede their germination, cut them off when above the soil, have ready a few dry furze or spruce branches in readiness to scatter along the ridges. As the Prince Albert, though the earliest, is by no means a great bearer, nor yet a fine-flavoured Pea, sow for succession greater breadths of the early Warwick, Frame, Bishop's Dwarf, and Shilling's early Grotto, and follow the Mazagan Beans with the best varieties of the Longpod and Windsor.

Asparagus, Sea-kale, Rhubarb, Chicory, &c.—Keep a regular supply of all these. Where a family is constantly resident, it is by no means best or better to commence forcing earlier than your stock will enable you to meet the demand, until they can be got from the open garden. *Forcing.*—Fresh beds of dung and leaves will require to be put in operation for Radishes, Horn Carrots, Potatoes, and early Cucumbers. Take care to make your beds large enough for the latter, if you wish to avoid trouble and annoyance afterwards. Of course, all these objects can be effected much easier in pits heated by hot water. *Mushrooms.*—These beds out of doors will require to be carefully covered with litter, and mats, &c. To those who are fond of this vegetable, (and in many families it is deemed as essential to good cookery as the Onion tribe,) I would urge the importance of appropriating a house or back shed to the purpose, to be heated by hot water. A good supply will thus be easily obtained, and a great deal of pleasure enjoyed in witnessing their growth. A bed completely covered is a beautiful sight at this season of the year. With respect to the method of cultivation, I do not think I can add much to what has been stated in former Calendars. There is an able Paper on the subject from Mr. Hankin in last *Chronicle*, but there is nothing new as the system of using turf instead of loam. I have no doubt it would answer admirably in such circumstances as Mr. Hankin describes. He places "light" as the second requisite for growing Mushrooms, while I think they are better, and more appreciated by cooks for their whiteness when produced in comparative darkness. *Roofing.*—See that Cauliflower, in all its stages, Lettuce, Endive, stored roots, fruit, &c. are secured from frost; do not waste time in attempting to trench and thus bury frozen ground, but rather forward in-door operations, such as making stakes, tallies, straw covers, wattling hurdles with spruce branches for the protection of Peas, Potatoes, &c. Prune and nail in the days after breakfast, everything except Peaches, Figs, Vines, and Raspberries; the doing of which had better be deferred six weeks longer; wheel dung, drive soil, turn composts, and exercise judgment and forethought in regulating your operations according to the state of the weather, and recollect that if you wish to see your men energetic, able, and willing to push through labour in any emergency, you must study their health and comfort, by providing suitable labour in unpropitious weather. *In Conclusion.*—To my young friends I would say, as a general maxim, you may take the advice of an Edinburgh nurseryman, and "now thick and keep friends with the cook," but do not attempt the latter object, by inducing him or her to connive at or conceal your deficiencies, or you may soon find that you have trusted to a bruised reed, but attain that object by securing to yourself the honourable position of comparative independence, by the faithful and diligent discharge of your duties—by keeping an abundant supply—and by rendering it imperative on the man who serves the horse, to keep a regular account of all the garden produce, a memorandum, the knowledge of the existence of which will save you from many petty causes of annoyance.—*R. F.*

State of the Weather near London for the week ending Dec. 28, 1844, as observed at the Horticultural Garden, Chiswick.

The highest temperature during the above period occurred on the 31st, 1834—therm. 59°; and the lowest on the 4th, 1837, and 1st 1837—therm. 18°.

Notices to Correspondents.

The Reprint of Mr. PAXTON'S COTTAGERS' CALENDAR is now ready, price 4*d.* each Copy. An Index has been added to this present Edition. Parties wishing to have copies for distribution among their tenantry can have them at the rate of 2*s* for 1*s*.

Bees.—*Apiarius.*—Wooden hives ought to be made of good deal about 1 or 1¼ inch thick. The collateral hive is, perhaps the best, being three square boxes about 12 inches in depth, and 1 foot in width. The centre box should be stocked with a strong early swarm, and the hive should be placed in a sheltered situation, open to the south or south-east. If the hive is well defended from the weather, and shaded a little from the winter sun, it need not be removed to other quarters. The bees will survive the winter, provided they have plenty of store, say from 5 to 20lbs of honey, but as to quantity much depends on the weather. The Polish hive is of simple construction, and, at your request, I shall notice it in a future paper. As regards the "temperature most suitable for the breeding and storing compartments," I would mention that that of the first is of much importance. If hives were kept warm in spring by extra covering (and feeding if wanted), I think it would insure plenty of early brood, on which success depends. Much has been said concerning cooling the store departments in beehives, and various plans have been tried with but little success; for the bees always seal up the vent holes when they are most wanted. In hot weather shading, or a hole large enough to admit a common-sized cork open at the top of the hive is quite sufficient. If that precaution is taken the rest may be left to the bees themselves. However neat the appearance wooden hives may have over that of straw, still the latter have the advantage of resisting both heat and cold better, straw being a much worse conductor of heat than wood. If you choose straw hives on the Storyfing plan, let them be about 9 inches in depth, and 1 foot in diameter, and flat on the top, for the capes to rest upon. You might try the "Bar-hive," which is highly recommended by Dr. Bevan and Mr. Golding; but if you purchase fine novel hives, with various appendages, and, each, you must not expect "a return for a given outlay" equal to the Rev. W. C. Cotton's statement, viz., that "bee-boxes will pay what they cost in the first year, and leave some profit besides." Such profit cannot be had from bees in this country, nor yet in Wales or Scotland, where they can frequent the blooming Heather. *J. Wighton.*——*A Subscriber.*—In order to protect your hives from the attacks of mice, make the hole so small that they cannot get in; that is the only effectual way.

Camellias.—*T. A. N.*—Nothing bears the knife better. Prune them when they are breaking their leaf-buds in the spring.

Cucumbers.—*Melonia.*—Syon House, and Allen's Victory of Suffolk, are good kinds.‡

Foreign Fruits.—*Inquirer* asks if any one will give him some good method for packing exotic fruits and vegetables, such as the Guava, Custard Apple, &c., so that they will keep well during a voyage of two or three weeks. He asks whether they should be packed up when ripe, or in an unripe state?

Heating.—*G. N.*—Brick flues answer ill for bottom-heat, and are a nuisance; for there is no getting at them to clean them when choked with soot, as they soon will be. They will dry the soil as well as heat it. We should think it quite hopeless to expect to grow Orchidaceæ by such means. If your master will not use hot water for heating such a place as you describe, it would be better to advise him to go back to a bark-bed for his Orchidaceæ, and a wooden stage for his greenhouse plants. If any one, in your knowledge, "has done for hot water," as you say, he must be a very unskilful person, and quite unfit for an example.

Insects.—*A. T.* will find the information he requires in the history of the Earwig, given in vol. i. p. 580, of this Journal. *R.*——*An anxious Lady's* Scales are the Coccus Testudo. *R.*

Kidney Beans.—*A Young Beginner.*—They will do well enough where they are. If, however, you can get them nearer the light it will be better. We doubt whether the book you name will prove worth having. We shall know better in a month or two. Wait a little.

Manure.—*J. Moon.*—Parings of hoofs form a very durable and excellent manure; but it acts slowly. It will, we presume suit Orange trees. Sickly trees of that sort can only be recovered by repotting in very rich soil, cutting close in, and plunging in a good bottom-heat in the spring.——*S. E. Turnbull.*—We are not aware that any very extraordinary effect is producible by two parts of carbonate of soda and one of sulphate of soda. If you wish to try the experiment, use them at the rate of ½ lb. to a rod of ground.

Melons.—*Theta.*—The Sirdar Melon proved to be the same as the Cabul. I exhibited fruit of it at Chiswick, in June last; some of the fruit were excellent. If Theta will send his address to the office of this Paper, he can have seeds of it. *G. Fleming.*——*W. J. B.*—Cuthill's Early Cantaloup, and the Improved green fleshed, are two good early green and scarlet-fleshed varieties for immediate sowing.‡——*Melonia.*—Cuthill's Early Cantaloup.‡

Mistletoe.—*Mr. Oldham*, of Mansfield, is so obliging as to offer to give seeds of this plant to any one who will apply to him for them.

Names of Fruits.—*W. D. F.*—The Forme de Marie Louise has been fully ascertained to be the same as the Marie Louise, in the Garden of the Horticultural Society, and by fruit-growers in the neighbourhood of London. It varies according to situation; and even the fruit from adjoining trees will differ in appearance, quality, and period of maturity. If doubts are entertained of the identity of varieties, the best way is to graft on the same tree. ‖——*Chichester.*—Your Pear is the Old Colmar. ‖

Names of Plants.—*W. Todd.*—1, Jasminum gracile; 2, Hermannia incana; 3, Boronia alata.

New Garden.—*Clericus.*—The slope is too great for turf, in dry weather, if the land is apt to burn; if not it will not be too much. For a kitchen garden the slope is an advantage. Dig in the turf by all means. Plant as soon as you can. Cut your old spurs close in, and get some young bearing wood on your old trees.

Pine-Apples.—*A. B.*—You can maintain a steady bottom-heat for Pine-apples without tan, by hot-water gutters or pipes in a chamber, the latter extending underneath the whole bed. ‖

Sea-Kale.—*Subscriber.*—You *may* force it two years successively, but you should not do so unless it has made a very good autumn growth. Plant a new bed any time between November and February.

The Rose Garden.—*T. A. N.*—Yes.

Transplanting.—*C. F.*—Lose no time. Do what you have to do whenever the weather will allow you. December is better than January, January than February, and so on.

Miscellaneous.—*H. H. N.*—We are not aware of any instance of a Golden Pippin tree invariably bearing double fruit, and nothing else; if there be such a tree, we should be greatly surprised to find that scions from it failed to produce double Apples also. There is no accounting for the first case, and the second would be more unintelligible still. The first is, however, not without a parallel.——*Ficulus.*—An advertisement is the only course we are aware of.——*B.* will see the advertisement in this day's paper.——*Begonia.*—It is Hydrocotylifolia.——*W. S.*—We never saw the plan of pouring boiling water on Rose bushes tried, for the purpose of killing the larvæ of the green-fly. As has been long since stated, green-fly is readily destroyed on Roses by syringing with weak gas-water. There is no periodical, upon such subjects as you mention, which we should like to recommend. London's "d' Arboretum Britannicum" is very full of such information, as far as hardy plants are concerned.——*J. W. D.*—What sort of pepper do you mean? If you wish for information, you should be a little more explanatory.——*Inquirer.*—The Christmas Rose may be propagated by dividing the roots; but the plants should be well established before the operation takes place.‡——*A Subscriber* will find a receipt for killing the Mealy Bug in last week's Paper, p. 852.‡——*J. O.*—The Post-office order was received.——*X. Y. Z.*—Really we cannot answer such questions. Inquire at the coach-office.

VERY FEW CORRESPONDENTS NOW REMAIN WHOSE KIND COMMUNICATIONS ARE UNPUBLISHED. TO THOSE WHICH ARE STILL IN OUR HANDS WE PROMISE SPEEDY ATTENTION; FOR SUCH AS HAVE APPEARED WE OFFER HEARTY THANKS, AND WE CORDIALLY INVITE ALL TRUE LOVERS OF GARDENS TO CONTINUE WITH UNFLAGGING ZEAL THEIR CO-OPERATION IN THE PLEASANT TASK OF INTER-COMMUNICATION.

Erratum—We regret that an error was made by our Compositor in Mr. Waite's List of Seeds, inserted last Saturday. Nemophilia discoidalis, priced at 1*l.* 1*s. per gallon*, should be 1*l.* 1*s. per ounce.*

RAMS FOR RAISING WATER WITHOUT LABOUR, where a fall can be obtained. FOUNTAIN BASINS IN IRON, &c. 79, STRAND, LONDON.

J. F. BOE having purchased all the Patterns of Basins, Jets, &c. formerly belonging to W. Rowley, Fountain Maker to the Royal Family, is enabled to offer the above article in iron, which will stand the Frost and last for ages. A Ram and Fountain Jets fixed on the premises for inspection. Every kind of Garden and other Pumps, Well Engines, Baths, &c. Houses, &c. Heated by Hot Water.

The Agricultural Gazette.

SATURDAY, DECEMBER 28, 1844.

MEETINGS FOR THE TWO FOLLOWING WEEKS.
Wednesday, Jan. 1—Highland and Agricultural Society.
Thursday, Jan. 2—Agricultural Imp. Soc. of Ireland.
Thursday, Jan. 9—Agricultural Imp. Soc. of Ireland.

In closing our first Volume, we take the opportunity of heartily thanking those who have contributed to its pages. It is on its practical Correspondents that an Agricultural Periodical must depend for its real value. Its Editor may certainly speak authoritatively when he treats of the *principles* of the art; but when he descends to any department of its *practice*, he can only state his personal experience, and the circumstances under which it was acquired, and then he only occupies the situation of one of his own correspondents. We say again—it is on the number and qualifications of *these* that the value of an Agricultural Journal must depend. That periodical is necessarily the most useful whose pages are filled with communications of the experience of its readers in all the various circumstances of soil, climate, &c., to be met with in the district where it circulates. We can say, without boast, that we have readers on all the varying soils, and in all the different climates to be met with in the three kingdoms, and if we could induce a greater number of them to state the agricultural experience of their respective neighbourhoods, the usefulness of the *Agricultural Gazette* would be much increased. For, as we said at the beginning of the year—*then* only shall we consider ourselves to have made much progress in the course of usefulness on which we have endeavoured to enter when our readers shall have been brought to consider themselves as the members of one large Farmers' Club for mutual instruction, ourselves occupying the place of the mouth and the ear through which they may communicate with each other.

The value we attach to reports of local agriculture when qualified by a full statement of the circumstances which justify it, makes us regard, with particular satisfaction, the sketches of East Lothian husbandry by Mr. Sullivan, the last of which series is this day published in our columns. If the *Agricultural Gazette* had done nothing more in its first year's existence than clear up the misconceptions which have existed as to the state of farmer and farming in that celebrated county, no one need have blushed for it. We venture to assert, that for quantity of valuable agricultural information, in so small a space, these "Sketches" are unequalled by any district report of farming hitherto published; and any one may see if we are wrong, by examining the volumes on the several counties, called forth by the premiums of the Board of Agriculture. We may also point, under this class to the "Geo-Agricultural Notes of South Gloucestershire," by "M. S.," as clearly bringing out the influence of Geology upon Agriculture—a point which of late years has been deemed of considerable importance. Among the other series of papers which we have this year published, we may refer to the articles on the "Application of Chemistry to Agriculture," on rational principles, by C. R. Bree, Esq., of Stowmarket; the papers on the "Flax Plant," by Mr. Sproule; and those on "Black Horseponds and Liquid Manure," by Mr. Gyde, of Painswick, to show that our columns have been by no means deficient in useful matter. Much attention, too, has been excited amongst our readers during the past year, to the waste of home manure in the ditches and horse-ponds of farm-yards, and to the loss in foreign manure by adulteration. This latter, in particular, was shown to be carried on to an extent before unconceived of.

We have already made arrangements for the appearance, during the ensuing year, of many important papers, amongst the subjects of which we may mention Drainage, the Economy of Cottages, the Economy of Farm-buildings, the Weeds of Agriculture, &c., and these will guarantee a continuance of the usefulness which the Paper has hitherto possessed. Nevertheless, we must continue to solicit our readers themselves to enter upon the great task of mutual instruction. Our columns are always open to *details of facts bearing upon Agricultural practice.*

Many benevolent persons who make the welfare of the agricultural labourer their care, appear, some 60 years ago, to have expected as great advantages from the dibbling of Wheat as is now justly expected from the allotment system.

The origin of the practice, in Norfolk, is well known. A poor labourer, in order to economise seed in sowing a small patch of Wheat on the plot of ground attached to his cottage, planted it with the dibble. The produce was so great as to attract the attention of the neighbouring farmers, by whom the experiment was repeated on a larger scale with such success as to lead to the extensive adoption of dibbling in the practice of that county. Great efforts were made to extend it to others, by philanthropists, in order to increase the amount of agricultural employment and human food—by the political economists, to render the labour of women and children a source of national wealth, in imitation of the system adopted in our factories at too dear a rate. These efforts, however, met with little success; they were opposed by the usual *visinertia*, and the usual objection of, "It may do *there* but it will not do *here*." The strong soils were considered too wet for dibbling; the dry soils as not possessing sufficient strength to enable the plant to tiller. Even in Norfolk the dibbling of Wheat appears soon to have reached its culminating point, for when Arthur Young made his report to the Board of Agriculture, early in this century, he described it as on the decline.

An objection to the practice, which we have recently heard urged against it, has probably some weight, namely, that it can only be well performed in the early part of the season; for as the weather becomes cold the droppers cannot feel the grains, and deposit too many in a hole. We know not whether a desire to increase the means of giving employment in agriculture, combined with the fine autumn we have enjoyed, to cause a more extensive adoption of dibbling this year than usual; but from our own observations in East Norfolk, we should estimate that full one-third of the Wheat crop in that district is put into the ground in that manner. The preparation of the ground is the same as for drilling. The dibbling is paid for by the acre, at the rate of 7*s.* to 8*s.* for dibbling and dropping. The lower price is, for broken ground, the higher for that put in on the whole "flag:" 1*s.* 6*d.* a-day for men, and 6*d.* a-day for women, is the current rate of wages in the district. The dibbler usually employs his own family for the dropping. Two droppers to each dibbler is the general proportion. The dibbles are of iron, about 4 feet long; the workman bending his back uses a dibble with each hand; he makes the holes about one inch deep, the distance between the holes being sometimes 4 inches each way, sometimes 4 inches in the rows, and the rows in pairs 3 to 4 inches asunder, with an interval of 6 inches between each pair.

On counting, in numerous fields, the spears issuing from the ground, we found that rarely less than four or five grains had been deposited in a hole, and not unfrequently more than 10. Even under the disadvantages of crowded plants which thus arise, the superior strength of the stubbles of dibbled over drilled crops is very obvious. There are in this district no broadcast stubbles with which to compare them. The saving of seed by the process thus conducted is not very great, 10 pecks an acre being the quantity usually drilled, and a little less, or when more precise information can be obtained, 8 pecks an acre, when dibbled. A large farmer, who dibbles none himself, from the difficulty of having the dropping well performed, declared to us, that if any method could be devised to insure the deposit of one or two grains in each hole, he had no doubt that this way of sowing Wheat would be superior to all others. Now, two grains to a hole, at the above distances, amount to no more than two pecks of seed to the acre; so that it is easy to calculate the saving which might be effected were even three pecks used, in order to provide for casualties. The difference between three pecks an acre dibbled and ten drilled amounts, on a farm of 400 acres, cultivated on the four course rotation, to 175 bushels. The difference between three bushels an acre sown broadcast and three pecks dibbled is 225 bushels. The saving in money, at 6*s.* the bushel, is 52*l.* 10*s.* in the one case, and 67*l.* 10*s.* in the other, or 2*s.* 7*d.* and 3*s.* 4*d.* an acre over the whole farm, 13 or 16 per cent. on a rental of 20*s.* This saving is independent of the increased produce to be obtained by dibbling, which, to put it in the least favourable point of view, more than compensates for the increased expense of the process over drilling and broadcast sowing.

The dibbling-machine invented by Mr. Newberry, of Hook Norton, Oxfordshire, appears to fulfil the conditions of thin and regular dropping, insisted upon as necessary to secure the superiority of this mode of sowing. The price of the implement is high, but on a farm of 400 acres the saving of seed pays for it in one season on the Wheat crop alone. This explains the great demand which we know to exist for the implement; and it may safely be predicted, that by its aid the dibbling system will make much more rapid progress in every part of England than in that in which it commenced, more than half a century ago. On dry soils, there can be no doubt that this is the best way of sowing Wheat. The inventor of the dibbling-machine uses it on clay. To Barley, Oats, and Tares, dibbling is as applicable as to Wheat; and for spring crops, there is less to be feared from it on stiff soils. Nothing contributed so much to promote the extension of drilling as the system of travelling drills owned by professional drillers, performing the work by the acre for those farmers who, by reason of the small size of their holdings, or their want of confidence in a new practice, were unwilling to purchase so expensive an implement. We would therefore suggest to landlords, Agricultural Societies, and others anxious to promote the diffusion of improvement, and to encourage the agricultural labourer, the propriety of purchasing, against the approaching spring, a few of these machines, to be placed in the hands of meritorious labourers, who shall dibble by the acre for the farmers, and pay for the machine by instalments. Care, however, must be taken, for obvious reasons, not to introduce too many into a district, while the practice is in its infancy.—*E. W.*

AGRICULTURAL EXPERIMENT.

(*Continued from page* 858.)

The only other experiments which I have to record at present, are some which were designed to test the advantage of steeping seed, both alone, and combined with the other advantages of being hoed, and of being watered with different proportions of the same solutions in which it was steeped. Four breadths of ground adjoining those last mentioned were sown with 20 rows of Wheat in each, and each was divided into four parts; in the first five rows, the seed was previously steeped for 24 hours, and nothing more was done; in the second, besides the steeping, the intervals were hoed; in the third, a solution of 8 oz. of the salt in which it was steeped was added on the 13th of April; and in the fourth, a solution of 4 oz. at the same time, in 9 gallons of water, but these two last portions received also additional hoeings; the third was hoed twice, the fourth three times. This perhaps complicates the experiments too much, and introduces some uncertainty into the results; however, it is necessary to state the facts: the dimensions of each portion were 36¼ square yards; the quantity of corn sown in each was a quarter of a pint:—

	Weight of Corn.		Weight of Straw.		Quantity of Corn.		
Nit. of potash.	lb.	oz.	lb.	oz.	gall.	qt.	pt.
1 not hoed	10	2	20	4	0	5	0¾
2 hoed once	11	6	21	8	1	2	0¼
3 twice, 8oz. sol.	13	5	23	8	1	3	0¾
4 thrice, 4 oz.	15	5	25	7	2	0	0¼
Mur. of ammon.							
1 not hoed	14	2	24	4	1	3	1¾
2 hoed once	15	2	25	4	2	0	0¼
3 twice	17	12	27	14	2	0	0¾
4 thrice	16	10	26	12	2	0	0¾
Phos. of potash.							
1	17	3	27	4	2	1	0¾
2	16	10	26	12	2	0	1¾
3	16	0	26	2	2	0	0¾
4	16	10	26	12	2	1	0¾
Sulph of soda.							
1	16	4	27	6	2	0	1¾
2	17	2	27	4	2	1	0¾
3	19	15	30	1	2	3	0
4	21	2	31	4	2	3	1

In order to explain the remarkable inferiority of that part on which the nitrate of potash was employed, it is necessary to observe that one end of that land was entirely overshadowed by a large Apple-tree, which deprived the corn of its food from light, and air, and earth; and therefore its produce cannot fairly be compared with the others; but its own sections, being all under the same circumstances, may be compared with one another; and the comparison shows that the hoeing was of use—probably as often as it was repeated, but how much, it is impossible to determine, on account of the solution with which 3 and 4 were watered. One thing, however, is clear, that the increase, which bore some proportion to the number of hoeings, was in no proportion to the quantity of solution which it received, but rather in an inverse ratio; and so, too, with respect to the sulphate of soda, which was much the most efficient of these manures, and in one instance gave a return equivalent to more than six quarters per acre; the same progression may be remarked, but not at all in conformity to the quantity of it used. The muriate of ammonia, indeed, seems to have observed a different law, and the ascending scale is more governed by the quantities of the manure, but still No 2 affords the same evidence of the beneficial effects of stirring the soil; the only exception is in the instance of the phosphate of potash, which is a most anomalous and inexplicable case; for it would seem, not only that hoeing was injurious to it, but that an addition of the same solution was equally injurious, and a further addition more injurious still: and yet, that the saturation of the seed with the salt was so beneficial as to raise the produce higher than any of the others. The only inference that I can draw from this is, that there was some local peculiarity in the composition of the soil, which modified the action of ordinary causes; and if this be so, the utility of a practice which has lately been much recommended, the practice of sending to a chemist for analysis a handful of soil selected for a sample, must appear to be extremely doubtful; the elements of vegetation

are scattered so unequally through the soil, that such investigations are encompassed with fallacies and uncertainty; and even if their combinations most favourable or adverse to fertility were certainly determined, which they are not, still the discovery of their existence in one patch of ground would be no guarantee of their presence a yard beyond it. I allude not so much to those palpable differences which may be observed by the eye, such as the alternations of sand and clay, which are not uncommon, but rather to those minute homœopathic doses of some of the rarer ingredients, which, it may be, are essential to fertility, and of which the quantity, and sometimes the existence, can only be detected by long and laborious research; and yet all this expense of time and money and toil would be useless (unless it could be repeated for every rood—I had almost said every rod—of land upon a farm), to prove that the facts so discovered were not confined to some trifling locality. Nor, if some prevailing deficiency were discovered, would it always be easy to apply a remedy; for the operations in the laboratory of nature materially vary from those which we employ, and the ingredients might not be combined, in any addition which could be made, exactly in the same proportion which is necessary for the production of the same effects. Nevertheless, although the farmer must not expect immediate assistance *from* this quarter, yet I am fully convinced that ultimately, by long perseverance and many analyses of the most fruitful soils, patiently and skilfully conducted, the chemist will arrive at some general truths, which will throw important light upon those principles of agriculture which are now involved in obscurity; and with a view to present benefit, if he can only show within what limits and in what forms lime and iron are essential to fertility, they being easily within the grasp of a rude analysis, the farmer will soon see his way more clearly into the causes of plenty or barrenness in his fields, and will be more ready to avail himself of the means within his reach to cure defects which are not beyond his comprehension, nor beyond the hope of remedy.—*L. Vernon Harcourt, West Dean House.*

SKETCHES OF EAST LOTHIAN HUSBANDRY.

Conclusion.—The reader who may have honoured these cursorily-written Sketches with a perusal, must have perceived that my object has not been to hold up the system of farming pursued in this locality as a model of judicious husbandry for general imitation, or as suitable for introduction into districts dissimilarly circumstanced. I have throughout, for the most part, contented myself with a simple statement of facts. This course I considered more satisfactory than that so frequently adopted by tourists, of publishing extraordinary and often extravagantly enormous statements of produce and profits, without at all entering into the details of the grand system of cultivation by which such startling results are represented to be realised. East Lothian is, no doubt, a highly-cultivated district, and occupied by respectable and enterprising farmers; but still the system of management adopted there is in many respects susceptible of great improvement. The statements of produce given in connection with the cultivation of the different crops may strike many of my readers as contrasting strangely with the ideas they had previously formed on the subject; but after diligent and repeated inquiries, as well as from personal observation, they will be found to be perfectly correct. On another occasion I hope to be able to place before the readers of this Journal a statement of the actual results obtained from individual farms on each of the several classes of soil into which the county is naturally divided; and in this paper I shall introduce a few general remarks on the system of management which I have hitherto so minutely described.

The soil and situation of any district properly exercise an important influence in determining the precise course of management which can be most profitably adopted, the former consideration, for the most part, determining the class of crops to be cultivated, and the latter the manner of their disposal. Wheat has been seen to be the staple crop of the East Lothian farmers, the strong tenacious soil there abounding being peculiarly suited to the Wheat plant; but by the more general adoption of the various improvements recently discovered, it is believed that not only might an increased produce be obtained but a greater diversity of cropping might also be introduced. Though naturally very fertile, the general character of the soil is a stiff, tenacious clay, in its present state difficult and disagreeable to labour; commonly requiring four or five ploughings, and an endless number of rollings, harrowings, grubbings, &c., even in favourable seasons, before it can be sufficiently pulverised and prepared for a Turnip crop; while in adverse seasons, such as that of last year, it is almost impossible to labour it to any degree of perfection. In its natural state it retains water like a sponge, and when once thoroughly saturated with it, requires a long time to become dry and ready for working. Hence draining and subsoil-ploughing are important primary operations before the resources of the soil can be fully developed; but although the former of them has been long practised to a greater or less extent, the great and essential importance of perfect drainage, and a thorough pulverisation of the soil, is not so generally appreciated or carried into operation as it is desirable that it should be, and hence a principal cause of the comparatively low produce frequently obtained, notwithstanding the superiority of the management in other respects.

In too many cases, the system of drainage effected by stone drains and open furrows is still the only method employed for the removal of superfluous moisture; nor is pulverisation carried deeper than the ordinary furrow-slice in ploughing. The system of parallel drainage is efficiently carried into operation in some cases; but even here erroneous ideas seem to prevail in reference to the means by which these effect the desired purpose. Wherever this system of draining is required, the action of the subsoil-plough is necessary to insure perfect dryness, it being no less necessary to provide the means for the water to enter the drains than to carry it off afterwards. The general prevalence of erroneous ideas on this subject can alone account for the trouble taken after drainage, even when it has been properly practised, to insure the open furrows of the field being directly over the drains, to facilitate thereby the water finding its way into them, as described in my paper on the subject in the *Gazette*, p. 395.

It is almost incredible that subsoil-ploughing has made so little progress among the East Lothian farmers, especially when it is considered that their soil, of all others, is that likely to benefit most from the operation. The use of the subsoil-plough may, indeed, be regarded as among the most important improvements which have recently been effected in British agriculture; for without it, as already observed, drainage is incomplete. When this circumstance is taken into consideration, it will not be regarded as surprising that the summer fallow should still be regarded so essential as a preparation for the Wheat crop—a process which, whatever may have been its advantages under former management, is now very properly regarded as unnecessary wherever the use of the drain and the subsoil-plough is properly understood.

The necessity of deep pulverisation to facilitate the escape of moisture contained in the soil into the drains has on former occasions been so forcibly brought before the readers of the *Gazette*, that it is scarcely necessary to enlarge on it here. An important result of the removal of superfluous moisture from the soil—the production of increased temperature in it—does not, however, seem to be generally understood.

The first and most obvious result produced by perfect drainage, by means of the frequent drain system and the action of the subsoil-plough, is the comparative facility with which the usual operations of husbandry can afterwards be performed at almost any season, and without any injury to the soil, unless while rain is actually falling, or immediately after. How often is the proper period for sowing unavoidably allowed to pass before the seed can be got deposited in the ground, owing to the unfavourable state of the soil! This is a circumstance with which the East Lothian farmers are familiar; and it is scarcely necessary to add, that it is almost invariably followed by a scanty crop; but even on wet soils, when, through the intervention of a favourable season, the seed-time may not be unnecessarily delayed beyond the proper period, how often may the crop afterwards be seen to languish and assume a sickly hue, in consequence of the saturated state of the soil on which it is produced! In dry seasons the value of perfect drainage is not so fully appreciated; nay, in such cases, it is too commonly supposed to aggravate the evils of drought; but the reverse of this is the fact. The evils of drought on the growing crop are greatly aggravated by the fissures thereby produced in tenacious soils, which still further contribute to facilitate the escape of whatever moisture may still remain in them; but it will be invariably observed that land saturated with moisture during the winter has the greatest tendency to suffer from this cause in the summer. Perfect drainage, therefore, instead of aggravating the evils of drought in the summer season, contribute more than anything else to alleviate them.

But one of the most important results of dryness in the soil is the increased degree of temperature thereby produced, the beneficial effects of which on vegetation, as contributing to increase of produce and early maturity, are sufficiently well known. As rain falls from the heavens it must either escape by subterranean channels or by evaporation. On certain geological formations, such channels are formed by nature, the substratum abounding in innumerable natural fissures, through which the water is carried off almost as quickly as it falls; and whatever may be the natural fertility of such soils, they are invariably distinguished by the comparatively early period at which the crops produced on them are ready for being harvested. Wherever such channels do not naturally exist, they must be formed by art before the productive powers of the soil can be fully developed. It should be constantly borne in mind that the smallest portion of water cannot escape from the soil by evaporation without the abstraction of heat. Every one must be familiar with this effect in the case of allowing the hand to become dry by evaporation after immersion in water, and the sensible degree of cold thereby produced; and, if alcohol or ether be substituted for water, the cold produced by evaporation will be much increased, in consequence of the rapidity with which these substances pass into vapour; indeed, so great is the degree of cold produced by the evaporation of ether that it may readily be made to convert water into ice in the warmest day in summer, the water in this case being merely placed in a thin glass tube, and the ether being made to fall on the outside in drops. Water evaporates more slowly than ether, and hence its effects in causing a diminution of temperature are not so apparent, the loss of heat being extended over a greater interval of time.

The maximum degree of heat in the soil is therefore produced when the greatest possible facility for the escape of the moisture contained in it has been secured. In a well drained field a day will, in most cases, be sufficient to carry off the water which may have fallen the preceding one in rain, leaving little to be carried off by evaporation; but in undrained tenacious clays, where evaporation is the only means of carrying off the moisture, the soil will often be completely saturated for weeks after heavy rains, and while it is in this state none of the ordinary operations of tillage can be performed on it, without imparting to it a degree of tenacity which it will require much subsequent labour to remove.

There are many of the details of East Lothian husbandry well worthy of imitation, and which might be advantageously introduced into other parts of the kingdom; but in the department of agriculture, now the subject of consideration, there is no question but the East Lothian farmers have much to learn, and considerable exertion to make before they are on a par with less highly favoured districts. If the subsoil-plough had been judiciously employed in conjunction with the drain, not only would the position of the furrows of the field, in relation to the drains, be a matter of perfect indifference, but open furrows would, in fact, be altogether unnecessary, the whole being in that case advantageously laid quite flat, without the intervention of ridges of any kind. The waste in cropping occasioned by open furrows, as well as the diversity in the quality of the produce thereby occasioned, are familiar to every farmer. Occasionally, it is true, a field so laid down may be seen in this district, but the practice is not general; nor, in fact, can it be so until more effectual means are extensively employed for drying the soil. Much of the soil of East Lothian was drained with tiles before the use of the subsoil-plough became generally known, and the drains then made being seldom more than 20 inches in depth, the use of that implement was afterwards inadmissible without destroying the drains; and hence a principal reason of so much of the surface of the county being now in an imperfectly drained state.

In conclusion, I may be allowed to state that if the Sketches of East Lothian Husbandry, which have now occupied so much of the space of this Paper, shall have had the effect of correcting misstatements, of removing erroneous impressions, or of contributing, in any degree, to the improvement of agriculture in less favoured districts, my object in their preparation will have been attained.—*T. Sullivan.*

ON GYPSUM AS MANURE.

It has been mentioned before, that gypsum is now strewed with great effect over the dung, and ploughed under with it; we may be assured, however, that this operation will especially succeed in dry localities and dry seasons; because, as the gypsum requires 450 parts of water for its solution, and the now formed sulphate of ammonia merely 4 parts of water, the plants will, in this case, be the surer supplied with the required sulphuric acid. It is advantageous, on the same ground, if gypsum (as it is done in some places) is mixed with the dung in the stables, or in the dunghill. He, however, who asserts that gypsum can only operate if previously decomposed by ammonia, is in error, because it manures well, even when the soil contains no ammoniacal salt which could decompose it; nay, we see that it acts powerfully, even if merely lying on the leaves, and solved in the water of dew.

It has been also often asserted that gypsum acts advantageously on vegetation only, because it constantly attracts water from the air, and thus supplies the soil with it. A trifling experiment, however, can convince us that this assertion is groundless. If a certain quantity of dry earth be mixed with a little powder of gypsum, and another be left by itself, we shall find by repeated weighings, that that portion which has been mixed with gypsum has not attracted any more water from the atmosphere than that which is unmixed. Fresh-burnt gypsum, it is true, attracts 21½ per cent. of water; but it does not give it up to the earth, but fixes it chemically.

If it is the case at times, that one coat of gypsum is more effective than another, it will be because it has been better burnt; it is especially important that it be not too much burnt, else it will become vitrefied, and soluble in water with difficulty. The few useful substances which it contains are of no consequence, because as only 80 to 90 lbs. of gypsum are used on the acre, the former cannot exercise any important effect on vegetation. It is, however, possible that gypsum, which contains much sulphuret of calcium, may be one of striking effect, as plants can then assimilate the sulphur and calcium without previous de-oxidisation. Some assert, also, to have found by experiment, that the sulphuret of calcium, which is formed by the influence of the carbon on gypsum, during the process of burning, improves vegetation to a considerable degree. It is natural that the fine dust of gypsum will dissolve easier in water than its coarser grains, as the former affords more points of contact to the fluid. It therefore is another instance of one sort of gypsum acting more powerfully than another; this may be caused by its different degree of pulverisation.

As it acts especially on the formation of leaves, the crops of Beans, Peas, and Vetches, which have been manured with much gypsum, will yield much straw, but little additional grain, as the former will grow on without producing any husks; for the sake of avoiding which, no more than 20 lbs. of gypsum ought to be used on some sorts of soil. Gypsum will avail most plants belonging to the families of the Leguminosæ and Coniferæ, which is easily explained by their containing many vegetable substances, into whose chemical composition sulphur enters to some amount. It is less useful to the Cerealia, and Buck-wheat does not derive any benefit from it at all; to Maize, on the other hand, it is very useful. It operates very quickly, because Clover, manured with gypsum, can be recognised even after eight days, by its

dark-green colour. Such Clover, however, must be given to cattle with some caution, as they become easily inflated thereby, which is, doubtless, caused by the great amount of sulphur the plants contain, as it is known that the gas, which mostly causes inflation, is sulphuretted hydrogen. If gypsum is strewed over the Clover, sown amongst Oats or Barley, immediately after the former has germinated, it will, at times, grow so luxuriantly as to choke the crop; the same will at times take place after the burning of turf, viz., if the ashes thereby obtained contain much gypsum. Once, after burning turf, planted Clover amongst Oats, which flowered the first year, and was 5 feet high.

It has been also found that the straw of Peas, Beans, or Vetches, which had been manured with gypsum, had given horses the colic; and it was believed to have been caused by the gypsum which had passed into the plants. Still, this may only have resulted from the crops (most luxuriant after that manure) not having been properly dried before being brought into the barns, and that the cholic was caused by the mould thus generated. It may be taken as a general truth that all crops, grown after gypsum, are more nutritious than usual, as sulphur is one of the essential components of the animal body.

Gypsum, applied in the usual quantities (80 to 100 lbs. per Magdeburg acre of land), acts merely for 3 to 4 years, the reasons of which have been stated above. It is never necessary to use large quantities, partly because gypsum is easily soluble in water, partly because the plants require but little sulphur for their perfect development. In some places Clover is manured after every crop; but then, every time but a very little is taken, which deserves to be imitated, especially in cases when the subsoil is very pervious, because then the gypsum solved in water would be quite lost for the crop, with the exception of Lucerne. There are yet some other mineral substances containing gypsum, which are used as manures, viz., the pan-stone and thorn-stone of salt works, which are obtained by the boiling and evaporation of the salt ley, and have long been known as superior manures.

a. The pan-stone consists, according to the chemical analysis to which I have subjected it, of 60 to 70 per cent. gypsum, at times 10 per cent. common salt, little chloride of potassium, sulphate of soda, oxide of iron, and magnesia. [Analysis will give very different results in different specimens.] Although, therefore, the pan-stone owes its manuring properties chiefly to gypsum, it is to be observed that the common salt also will exercise some influence. The other substances can avail the plants but little, and they are contained in it but in small quantities; and as, moreover, the quantity of pan-stone brought on a certain area is so trifling that it cannot be expected to exercise any great influence.

On some soils the manuring with pan-stone, like that with gypsum, will be quite useless, whilst on others it will be exceedingly beneficial. Similar effects always follow similar causes, and it is clear that pan-stone can produce no effect on soils which possess already a sufficient amount of gypsum and common salt, as the plants have previously satisfied their want of these two mineral substances. It is also to be considered, that the amount of pan-stone used (100 to 120 lb. per acre) conveys not sufficient common salt on the soil for producing any extraordinary result, as we shall see afterwards, that at least 110 lbs. common salt must come on an acre, if the result shall be favourable, and that area will obtain through 100 lbs. of pan-stone (assuming it to contain 10 per cent.) only 10 lbs. of common salt.

Pan-stone will prove itself useful to all plants to which gypsum is of some use, this being its chief manuring substance. It will especially advance the growth of Peas, Beans, Vetches, Lime, &c. Previous to its being used, it must be carefully pulverised, which will cause much trouble, if it be not done in a stamping-mill. It is generally strewed over the young Clover, or the young crops. If it contains (as is at times the case) much carbonate of lime, magnesia, &c., a greater quantity than that above stated is to be employed.

b. Thorn-stone is either beaten off the thorns which have been used for the refining of the salt ley, and around which it has formed a hard crust, or they are burnt, after which they are pulverised and used as a manure. It consists, as I have learnt from several experiments, mostly of gypsum, as it contains only 5 per cent. of carbonate of lime and magnesia, silica, iron, &c. If the thorns are burnt, they manure, as a matter of course, also by the ashes of the wood. It is used like gypsum, and will avail all leguminous plants, Clover, &c., in the same way as the former.—*From the German of Professor Sprengel.*

Home Correspondence.

The No-pasture System.—No one can be a greater advocate for abolishing permanent pasture than myself; and I am convinced, from experience, that milch cows and working horses are kept most advantageously by being soiled; but Mr. Mechi ought to tell us that he has found, experimentally, that young cattle and colts can be reared equally well by soiling as by pasturage, otherwise his system must be faulty. It appears to me, also, that there is an objection to his favourite Lucerne and Saintfoin, inasmuch as they interfere with rotation, and are almost as bad in this respect as permanent pasture. In other points they are certainly superior to the Clovers, as, when established, they make us more independent of the seasons, and afford a more frequent cut. On the failure of the Clovers, we have no alternative but Vetches. Mr. Mechi has, I think, said that he cuts all his green meat into short lengths. Does he do it by hand or horse-power? If the latter, with how many knives? I have broken a one-horse power machine by attempting it, owing to its clogging. Is there any good reason for a cow giving more milk when the hay she eats is cut into inch lengths, or when given uncut?—*W. C.* [We know of none, excepting that the process of digestion may be more effectual when the food is administered in a somewhat reduced state. There is not that reason for reducing the food of animals that chew the cud, that there is in the case of the horse, and others which do not.]

Failure of Oats.—I am a reader of your very valuable Paper, and have seen several articles which I approve of upon rotation of cropping, but have met in neither anything accounting for the deficiency of a crop of Oats in some parts of fields, whilst in other parts of the same field a good crop is produced. This failure is by some farmers called "blowing," that is, the Oats grow until the ear is about formed, when it begins to assume a stunted and withered appearance, and consequently comes to little use. It generally happens after ley; but when the ground has produced a crop of Potatoes or Turnips, and is properly cleaned, the Oats after are a good crop. Is it a deficiency in the soil, or is it a weed which robs it? I am inclined to think that it is the latter, as the spots are much overgrown with plantain, &c., and likewise the failure happening after ley. Would Beans answer in such parts after ley? Here we sow Beans after Turnips, along with Grass-seeds. Be so good as to state what is the cause of failure of Oats, and if Beans would grow after ley in such soil. Our soil here is, for the most part, a stiff loam.—*An Aberdonian.*

Experiments on Nutrition.—The experiments of Boussingault with his two cows fed on Mangold Wurzel alone, are somewhat akin to those made by his countryman, Macaire, on plants, some years ago, when the excretionary theory was propounded. In both cases the subjects experimented on were placed in such a state that disease was sure to be the consequence; in the one case the fatty matters found in the milk and the excrements of the cows were proved to be produced at the expense of the fat previously deposited in the animal tissues; so the much-talked-of brown matter found in the water in which Beans had grown (or rather had been soaked), would, there is good reason to believe, be found to be produced by the destruction of some portion of the tissues of the seed or plant. No experiment of this kind can be satisfactory unless it be so conducted that the subject experimented on shall be continued in a perfectly healthy condition. The experiments made by Earl Spencer, as detailed in the 2d vol. of the "Journal of the Royal Agricultural Society," were conducted on such a plan that the health of the animals was preserved. Barley when malted, will cause an animal to become sooner fat than when unmalted. Will the disciples of Messrs. Boussingault and Dumas inform us how this takes place?—*Inquirer.*

Gas-Water.—Having seen in your Paper lately an article recommending one of your correspondents to add gas-water to a heap of decayed leaves, &c., I intend to try the plan; but on going to the gas-works I found that there are two sorts of gas-water—one, a sort of brown oily substance, which distils from the gas, and from which, I believe, they make naphtha; and another, lime-water, which is used for purifying the gas. Now, would you be good enough to inform me which I should use, and what quantity for a heap of about six cubic yards, and oblige an—*Amateur.* [Two or three hundred gallons of the former, which is the *ammoniacal liquor*, should be applied per acre; if you intend to apply these 6 yards of leaves on an acre, soak them with that quantity.]

Guano versus Farmyard Dung.—At a time when so many conflicting opinions are afloat respecting the fertilising properties of guano and other manures, I think it but right that every one who has the opportunity and the will to try experiments in this way, should give to the public the result of such trials; and having no doubt but that the following particulars will be of interest to some of your readers, I with pleasure record them, with a further promise to report also the result of other trials now in progress. Last spring, to test the efficacy of guano as a manure for Potato crops, and also to try its relative merits with good farmyard dung, I dressed about an acre and a half with guano, at the rate of 6 cwt. per acre, at a cost of 3*l.* 18*s.* per acre; sowing it in the drill, and covering lightly with mould before planting the set. I also had drills opened and the dung laid in; the set being planted on the dung. In order to bring the expense of manuring per acre as near as possible to each other, I manured with dung accordingly, thereby giving what we here term a good dressing: the land is rather poor, inclining to a peat. Those sets planted on the guano showed a very marked superiority in their growth, even up to the very day of digging, when the result fully realised my most sanguine expectations, and justified me in my previous predilection for this new-fashioned fertiliser, by giving the following return*:—

No. 1.—Short row.. Dung 6 bsh. 6 galls.
No. 2.—Ditto .....Guano 3 bsh. 2½ galls.

Thus giving a difference of 1 bsh. 4½ galls. in favour of the guano; and this superiority was very general throughout the whole crop. I have witnessed its very powerful effect upon Grass land. In the beginning of August, having selected a very poor miserable piece of lawn or pleasure ground, I applied a dressing of guano, at the rate of 5 cwt. per acre, having previously mixed it with a quantity of leaf-mould; the effect was instantaneous, for in less than a fortnight, the plot assumed a darker hue, and rapidly recovered from that sterile appearance it had for two months previously borne; and at the time of cutting, which was less than seven weeks after the application, the Grass had grown to fully 7 inches in height, and of a most healthy appearance, while the ground (for it could not possibly be called Grass) adjoining had more the appearance of a gravel walk than otherwise; and at this period (December 1st), the selected spot appears to have undergone quite a change, still maintaining its verdure-like appearance. In order to be quite sure that the leaf-mould had not a great share in the improvement, I dressed another plot from the same heap, but the continued dry weather prevented its having any beneficial effect whatever; consequently I was quite satisfied that the astonishing effect was attributable entirely to the powerful agency of the guano. —*Quercus II.*

Feeding Cows.—I keep two cows tied up day and night in the cow-house, except on fine days, when they are turned out into the yard for two or three hours in the middle of the day. I give them as much meadow hay as they choose to eat, and each cow has one oil cake, about 3lb., divided into three portions, for morning, mid-day, and afternoon. I have plenty of Potatoes—200 bushels at the least—but no apparatus for steaming, no copper large enough to boil the Potatoes in, and firing is very dear. My question is, May I venture to give the cows the Potatoes in a raw state? and if so, in what quantity? I have made many inquiries among the neighbouring farmers, and have conflicting answers. Some say, the Potatoes will do the cows no harm—others that raw Potatoes will ruin the cows, make them poor, lousy, and the milk no better than mere water, with many other objections.—*Hatfield.* [The results of experiments on feeding with Potatoes, strange as it may appear, have as often been favourable to using them when raw as when boiled or steamed.]

Inclosure of Land from the Sea.—If the "Strathern Farmer" will refer to the *Agricultural Gazette* of Oct. 26, and the following Numbers, he will find inquiries made on the subject he is anxious to give information upon. In the case referred to he will see that the difficulty was to get rid of the superabundance of salt. It does not appear whether there was any great admixture of salt in the overflowings from the Tay—probably much less than in the case before inquired into, which related to a tide-river in the south of England. Having seen the Tay, I should suppose there was more fresh water in that noble river than in all the rivers that flow into the sea, in Sussex or Hampshire, at any time of the year, except, perhaps, in very wet winters, for during the dry months the quantity of fresh water, compared with what flows in by the tide, is very insignificant. After the tide is gone down, the water left in the pools is still so salt that common sea-weed flourishes in it. Of mud there is no deficiency, but, from the superabundance of salt in it, it is hardly fit for the purpose of manure by any process I know of. There is no doubt an alluvial deposit from the fresh water above the tide-way, brought down by heavy rains from the land above; but no land, fit for cultivation, can be gained from the river, as is described to be the case in the Tay. The directions as to the slope of the banks to the sea are very valuable. The sea has been excluded from about 30 acres, which in September last was very dry. It will be brought into cultivation whenever the best method of getting rid of the salt can be ascertained. Any information as to what will accomplish this will be thankfully received. The "Strathern Farmer" will perceive that I am enough of a Scotchman to answer his questions by asking another; but I conceive he is far more likely to know how to convert his reclaimed mud into corse land than I am.—*M. D. P.* ["M. D. P." shall soon have evidence on this subject from another quarter.]

Allotments.—Not long ago, a correspondent from Tottenham wrote in the *Agricultural Gazette* about the many difficulties in the practical working and letting of allotments, and especially as regards the trouble of getting them into one's own hands again out of those of bad tenants. I meant to have let some land for allotments this Christmas, but thy correspondent has alarmed me, and unless he can put me in the way of letting, so as to be safe, and so that they will require but little trouble, I must reluctantly decline. I think he says that he has managed allotments for 20 years; and if so, he surely by this time must have hit upon some well defined plan, and rules, and regulations, and agreements, by which the matter may be managed almost to a certainty. If he would furnish such to the world through thy Paper, it would doubtless be useful to others as well as to myself; or if he will not do that, perhaps he will communicate his plans and modes privately to me, through thy introduction. I hope to see something about it in next Number, or to hear from him this week, as the time is drawing so near when the labourers would like to begin, and I understand they are very anxious to do so.—*Robert Warner*, 8, *Crescent, Jewin-street, London.*

Hedgerow Timber.—I wish to call attention to the management of hedgerow timber, the early pruning of which is generally totally neglected; although from its unsheltered position it more especially needs judicious treatment. It is commonly left entirely to the discretion of such farm labourers as may chance to be, at intervals, engaged in making and repairing the hedges in which it stands. They, of course, seldom feel much in-

* I had not leisure to superintend the measuring of a larger quantity; but am quite satisfied, from my daily visits to the men, that the measured part bore a fair proportion to the whole.

terest on the subject, or can exercise much judgment respecting it. On many estates the timber is almost exclusively confined to the hedgerows, where it is very abundant, but has been suffered to grow up without the slightest attention to pruning. On every side trees of considerable magnitude may be seen spreading their limbs widely over the inclosures they surround, so low as, in many instances, scarcely to leave headroom for the plough teams; yet it is with difficulty that a tree can be found having a clear bole of sufficient length to be converted into plank for a barn floor, or even into materials for common field-gates. The total neglect of pruning hedgerow trees is a severe injury to the farmer. The massive heads of the trees reach almost to the surface of the soil, destroying that portion of the crop over which they immediately extend, and injuring the remainder by shutting out the light and air from them. It also leads to the wretched practice, wherever it is not strictly forbidden, of lopping off the lower limbs when of large size. This practice exists to a great extent; the limbs are commonly cut off at the distance of 2 or 3 feet from the bole, under the notion that the stumps will throw out young shoots, and thereby prevent their decay. This may be the case when trees are felled within a few years after having received such treatment; but if they remain standing for a longer period, some of these stumps must inevitably decay, and then they serve as channels to convey the falling rain into the bole, much to its injury. If landowners could be induced to give instructions that all young saplings standing in the hedgerows on their farms, should for the future be reared with clear stems of reasonable heights, and if these instructions were attended to at the periodical times of making the hedges, it would contribute equally to the advantage of themselves and their tenants; and at the same time put an end to this sad habit of lopping. Many timber merchants are altogether adverse to pruning. On my speaking of the subject to one of very extensive experience in the Wealds of Surrey and Sussex, he most emphatically said, that "it is better at once to cut down an Oak sapling, than to attempt to prune it; the Oak," he added, "will not bear pruning." Your correspondent, P. P., appears to have received a very similar reply from the Sussex timber merchant; he, however, ultimately qualified his opinion by admitting that you might keep a clear stem while the tree was young, so that you did not interfere with its top, thus assenting to nearly all that most advocates for moderate pruning would desire. It is doubtful whether much deference is due to the opinion of timber merchants on the subject. Their attention is almost exclusively directed to timber trees of mature growth; and they are too apt to attribute the defect discovered, in the conversion of timber, to the injurious effects of pruning, when, in truth, they should be referred either to the pernicious practice of lopping, to which allusion has before been made, or to the trees in which these defects appear, having been permitted to grow up so close together, that, for want of air, the lower limbs in time ceased to vegetate, and at length became rotten. It may be objected, that it would be folly to attempt to rear trees in hedgerows, with lofty stems; that, standing without shelter, they are naturally disposed to throw out a profusion of branches; and that, to oppose this tendency would be to combat against nature. It is not contended that we should aim at obtaining lofty stems; but that we should endeavour, by early pruning, to secure boles of such heights as may, according to situation, be reasonably hoped for, and be capable of forming valuable timber. Experience proves we need not despair of this.—*W. A.*

Potatoes.—I wish to reply to the notices which have recently appeared in the agricultural part of the *Chronicle*, casting doubts on the manuring properties of the Garnkirk fireclay for growing Potatoes. The experiment I reported was certainly made on a very limited scale, and, consequently, less satisfactory. For the accuracy of the details I communicated, however, I can vouch, on evidence that your correspondents will not question. [This was not in the least doubted; we only suggested the unreasonableness of inferring anything in agriculture from trials of such limited extent.] Mr. Sprot planted the Potatoes in presence of Archibald M'Neill, Esq., Director of Chancery, and others, who can attest the truth of what I stated as to the relative qualities of dung and clay used respectively. The produce of the four shaws was taken up in the presence of Capt. Marshall, of the Royal Terrace here, Mr. Sprot, of Garnkirk, Mr. Thomas Sprot, and myself. In answer to Mr. Goodiffe I may observe, that so far from the influence of the dung having extended to the shaws manured with fireclay, it was the shaw farthest off from the dung that gave the greatest return, the produce of which alone was more than both the dunged shaws put together. Suppose the figures 1, 2, 3, 4, to represent the position of the shaws, 1 and 2 being the fireclay, and 3 and 4 the dunged shaws; the shaw No. 1 was more productive than both Nos. 3 and 4. Yet I own the experiment was too limited. It will be put to the severest test next season; for not only Mr. Sprot, but his neighbour, Mr. Campbell, of Bedlay, and others, are to try it on a large scale, by growing, say three or four drills of Potatoes manured with clay, and three or four drills manured with dung alternately over the field. Let your readers have the kindness to await the issue, and till then suspend their judgment.—*N. Anderson, Maryfield, Edinburgh, Dec. 7.*

To get rid of Moss.—Fold your sheep on the parts overrun with it, and give them Turnips or Swedes, &c., to eat in troughs.—*J. B.*

Societies.

HIGHLAND AND AGRICULTURAL SOCIETY.

The first monthly meeting of this Society for the session was held on Wednesday last, under the presidency of Mr. Graham, of Balgowan.—Mr. Borthwick of Crookston commenced the business of the meeting by reading a report on the plantation made by the Duke of Richmond, on his estates in Aberdeenshire, during the last five years. The ground planted comprises the Binhill and adjoining moors, situated in the parishes of Cairnie and Huntly, and distant one mile from the town of Huntly. It extends 2¾ miles from east to west, and 2¼ miles from north to south, comprehending an area of 2258 imperial acres. The aspect of the ground is much diversified by irregular rocky hills. The surface is either rocky or occupied with very large earth-fast stones, which rendered it quite unfit for tillage, and had been pastured as a common by sheep and cattle belonging to small tenants and crofters. The soil is various. On the low grounds the soil is in some parts wet gravelly clay, retentive of water; in others of deep rich loam, damp, and even swampy; and at other parts it is of friable loam, on dry porous subsoil. On the high rocky grounds the soil is friable loam of good quality. On the braes along the base of the rising grounds it is deep and mellow. The vegetation consisted of benty Grass upon the wet retentive clay, green sward with long Heather upon the damp deep soil, and green sward and short open Heather upon the high rocky grounds. The land was surveyed, and a plan made in 1838, by Messrs. Beattie and Walker, land-surveyors in Aberdeen, and they also made out the specifications of the contract for fencing the grounds and planting them. The fence consists of a Galloway dyke of angular stones, built 3½ feet in height, at 6*d.* per yard, carriage included, at a cost of 464*l.* 4*s.* 3*d.* A number of open drains were made through the wettest parts of the ground, from 1 to 2 feet in depth, 12 inches wide at the bottom, and from 1½ to 3 feet wide at the top, at a cost in all of 225*l.* 15*s.* 7*d.* A road of 15 feet in width was made for the purpose of giving access to a moss from which the servants were in the habit of supplying themselves with peat fuel, and which cost 180*l.* The roads afterwards required for conveying away the thinnings of the woods, and the timber itself, will be made as occasions require. The grubbing of Whins and other plants cost 54*l.* 0*s.* 9*d.* The ground was subdivided into seven portions before being planted, and the trees which each division was to receive were specified in the contract. The first lot was planted with Scots Fir and Larch, 2 years' seedlings; the second lot with Spruce alone, 3 years' seedlings; the third lot with Scots Firs alone, 2 years' seedlings; the fourth lot with Larch alone, 2 years' seedlings; the fifth lot with hardwood, 4 years transplanted, consisting of Oak, Elm, Ash, Birch, and Beech, in equal quantities; the sixth lot with Larch alone, 2½ years transplanted; and the seventh lot with Scots Fir and Spruce, 2 years transplanted. The exact quantity of ground thus planted consisted of 2257 acres, 3 roods, 1 pole, with 6,387,017 trees. The contractors for planting the whole ground were Messrs. Lawson and Son, Edinburgh, Seedsmen to the Highland and Agricultural Society, and their contract price was 1956*l.* with obligation to uphold the plants for 4 years. The operation of planting commenced in March, 1836, was resumed in November, and finished entirely by the 20th of December of the same year, and the task was performed by from 50 to 80 men and boys. The cost of all the operations stands thus:—

	£	s.	d.
Estimate for planting	1956	0	0
Inclosing with a stone dyke	464	4	3
Making a road	180	0	0
Draining with open drains	225	15	7
Grubbing up bushes	54	0	9
Expenses of survey, &c.	76	12	11
	£2956	13	6

Giving an average cost of about 26*s.* per acre.

It seems that about 100,000 plants were required to fill up the blanks caused by ordinary failures during the four years in which the contractors were bound to uphold the plants; but as many of the plants had been placed in situations unsuited to their nature, though in accordance with the terms of the specifications, the blanks occasioned by their failure were filled up at an additional expense to the proprietor. For this purpose, 260,000 Larch, 340,000 Scots Fir, and 50,000 Spruces, were required. "It remains only to be added," concludes the report, "that during the past summer the plantations have made rapid progress, excepting in those portions of the ground where, from various causes, the plants have failed to some extent; and that the Binhill and moors adjoining it already begin to assume something of a clothed appearance." Mr. Borthwick remarked, that one might learn from the Paper which he had the honour to be appointed to read to the meeting, that although much attention had been paid to the drainage of the land, and to the prevention of the Grasses originally growing on some parts of it from choking the young plants, yet that a greater degree of precaution might have been advantageous. There are many instances of plantations being made, which have either failed, or, advancing in a feeble and languid state, have not made more progress at the end of ten or fifteen years than they would have done in four or five, had more time and pains been taken, before the act of planting, thoroughly to drain, cultivate, subdivide, and inclose the land. As appeared in the present case, considerable injury had been done to the young plants on the more fertile divisions of the land (where the hardwoods, the most extensive of them, were put), from being overlaid and killed by the Grasses. Mr. B. was of opinion that on such situations where the plough could be used, advantage arose from ploughing the land with a shallow furrow, and taking a crop of grain, for a season or two, so as to pulverise the surface, and remove the old established Grasses, the roots and stems of which, on land never before in tillage, or on old lea, formed a thick matting, which, as it were, thatched the ground, and thereby, unless in very wet seasons, prevented the rains from fully penetrating the soil. But by this preparatory process the humidity of the showers during the first season after young trees are planted reaches and invigorates their roots, which, soon striking into the subsoil, give them a firm hold of the ground. Where the land is so situated as that it cannot be ploughed, from steepness or otherwise, benefit might be derived from paring the land to some distance round the space where each plant is to be put.—The next Paper, on the Results of Comparative Experiments made by Mr. James Melvin, Bonnington, near Ratho, on Potatoes imported from different countries on the Continent, with the common varieties cultivated in this country, was read by Mr. Boyle, gr. of Shewalton. The foreign varieties consisted of two from Hamburg and one from Holland. They all had when planted an unpromising appearance, being small, even smaller than the out-riddlings in this country—green and watery when boiled—having a clear thin skin when washed, and showing a great many eyes. The soil in which they had grown had stained them with a brownish-black colour. Of the two varieties from Hamburg, one was white, the other pink; and that from Holland was white. They were planted in two fields, occupying in all fully a Scotch acre, in a manner precisely similar to the Potatoes of this country. The Hamburg Pink almost entirely rotted in the ground. The two white varieties manifested at first an unfavourable appearance, sending up puny shoots—every eye, however, sent up a shoot—and as most of the tubers had been planted whole, and the people, fearing to lose the crop, from their smallness, insisted on planting two together, and the number of shoots that came up crowding together, showed at once that the crop had been too closely planted. After the stems had risen about two feet they interlaced in the drills, and presented a surface of uniform levelness, and at length towered far above the common varieties in the same field. The Dutch White exhibited a white blossom, with a few seed-apples; the Hamburg White a beautiful purple and highly odorous blossom, but no seed-apples. The leaves of the Dutch sort had fallen, while those of the Hamburg remained vigorous and green when the crop was taken up. In regard to comparative produce, in one field, the Hamburg White yielded 12 tons per acre, while the common Dons gave only 6 tons, with 20 tons of farmyard dung and 3 cwt. of specific manure, of the value together of 7*l.* 7*s.* per acre. In the other field the Dutch White also yielded 12 tons, and the Dons 7 tons per acre, with 24 tons of farmyard dung, and 3 cwt. of specific manure, at a cost of 8*l.* 11*s.* per acre. The few Hamburg Whites which had been planted by accident among the Hamburg Pinks that rotted, having plenty of room to grow—about 4 yds. to each plant—their stems spread greatly about, and in taking up the crop, scattered as it was, each stem produced from 10 to 20 marketable Potatoes; others had as many large ones, with from 20 to 60 small; others had 90; and one had 102 Potatoes, from the size of a boy's marble to those of an ordinary-sized Potato. The Dutch White are the best to eat, but none of the foreign varieties are good for the table, being watery, though they seem well adapted for cattle, producing at least one-third more than either the Buffs or Dons. On another farm the Hamburg White gave from a sandy meadow 15¼ tons per acre; while the Dons only yielded 8¼ tons, and the Early-lates 9¼ tons. On a third farm from strong soil, but drained, the Hamburg White yielded 7 tons an acre more than the common sorts beside it.—Mr. Stephens then shortly described the Stone or Stubble-turnip, and exhibited some specimens sent to the Museum by Mr. Richard Makins, Shellacres, near Cornhill, in Northumberland. This Turnip possesses all the characters of the garden Stone-turnip, and may have acquired its larger size from having been cultivated in the fields. This Turnip may be raised with bone-dust or guano, like any other kind, and it may be sown as late as the 11th July, and yet afford a good-sized firm bulb by the beginning of the ensuing September, when they may be laid down on the stubble or lea for the use of the cattle or sheep. Mr. Stephens prefaced the description of the Stubble-turnip, with a few remarks on the utility of Rape for sheep early in autumn. It is raised like Turnips, and in order to avoid the inconvenience of ploughing in its strong stems when the consumption of Rape is delayed till late in autumn, he recommended portions of it to be sown at different times, so that each portion may always be in a young growing state, with slender stems, when the stock arrives to consume it. With the possession of Rape for sheep, and of Stubble-turnips for cattle, Mr. S. remarked that farmers themselves would be to blame should their stock want sufficient food early in autumn from the failure of the Grass, till the winter Turnips are led into the straw-yard.—Sir Charles Gordon, the Secretary, then intimated that he had received notice of the melancholy death of the celebrated M. Fellenberg, of Hofwyl, in Switzerland.

STURMINSTER AGRICULTURAL SOCIETY.

At the late Annual Meeting of this Society, at which Earl Grosvenor presided, the Rev. Mr. Huxtable, of Sutton Waldron, delivered an excellent speech, from which the following are extracts:—"Before I proceed to practical farming, I hope you will not object to my making an observation on the great question of emigra-

thing in reference to the labourers. I do not agree with those who consider emigration as the great panacea for the evils of the country, nor do I think, under present circumstances, that it is necessary to resort to this plan for the purpose of relieving us from what some term our redundant population. On the contrary, I am satisfied that, at present, in agricultural districts, we are far from having a surplus population, and that, instead of sending our labourers to a foreign land, away from their country and kindred—where there may be no dwellings for them, and where they would be without spiritual care, far from all churches, schools, and ministers of religion—we could profitably employ them in our own country. Why, my lord, I think, if the farms were cultivated as they ought to be, and if the necessary improvements were made, instead of sending our labourers out to Canada or other distant colonies, we should want to go abroad for labourers. And whilst this is true of our rural districts generally, it is emphatically true of Dorsetshire, where, in the Vale of Blackmoor, thousands of acres require draining, and where, on the hills, thousands of acres of down land might be profitably brought into cultivation. Let us consider the extent of labour that would be created in breaking up waste lands. Each fresh acre taken into cultivation would call, at least, for an outlay of 28*s.* a-year in labour; and although gentlemen may love to gallop over those beautiful downs without control, yet they should remember that there is in the valleys a loud cry for *labour*, and for *bread!* I do not object to the harmless and healthful recreations and sports of the country, but if we cannot employ our people in the valley, then! say, let us mount the hills. Is not, I ask, the demand for labour enough to move the sternest heart? What is it the destitute labourers ask from us? They do not come knocking at our doors, as idle mendicants, asking alms, but they ask for work. I have seen such men at the cross of my parish; and who can observe, in almost every parish, strong and yet peaceful men, standing at the cross-road, soliciting, not charity, but employment, saying, 'Here we are, sir, able in body and strong in nerve and arm; won't you give us work?' Who can see this, and not on his pillow revolve in his mind by what expedients this great power of our country, this noble race of fellows, more free from the taints of crime, more patient and enduring than perhaps any other class of their countrymen, may be turned to beneficial and practical uses? My own firm conviction is, that if we avail ourselves of improved arts of cultivation, remunerating labour may be found for all. First and foremost stands draining. I have executed many miles of drains 2½ feet deep, a perch apart, up and down the furrows, and I can truly state that, after the first season, the effect has been almost magical in the altered appearance of both soil and crops. No outlay, I am convinced, can produce so great a return. Why, then, do not gentlemen of capital employ their resources in this way? How contemptible, in comparison, those miserable 3 per cents. above par. The Kohl Rabi and some of the Wurzel shown this day in the yard, was grown on land which, before draining, was valued at 8*s.* an acre. Another means of employing our surplus population, as they are called, may be found in transplanting Mangold Wurzel, Swedes, and Kohl Rabi. The right practice is that the seed should be sown in a seed-bed, at the end of March or the beginning of April. As soon as the Vetches, Rape, Rye, or other winter crop is consumed, the land should be ploughed into ridges, and good dung laid in them, to be then covered over by splitting the ridges; after which the Wurzel, Swedes, or Rabi should be transplanted on them. This, I can tell you, is a certain means of obtaining a good crop, care being taken that the Wurzel be nearly as thick as one's middle finger. It is only the sickly plants which fail. The expense of this transplantation can never exceed 15*s.* an acre, even when, in drought like that of this year, it becomes necessary to make a puddle with liquid manure to receive each plant. On my hill farm, upon land which, when in down, was supposed not to be worth more than 2*s.* 6*d.* an acre, in the burning month of June, this year, whilst the chalk stones were quite hot, I succeeded in raising 12 acres of good Turnips, in utter defiance of the fly. The plan pursued was to mix the Turnip-seed with pig's manure, and then to dibble both together into holes made with a bean-setting stick. This, of course, employed many hands, but the cost was not more than 7*s.* per acre in labour; and I invite any one to inspect the crop, and then decide whether the employment of surplus labour be not remunerating. Generally, the plan of increasing the demand for labour is to grow more green crops, and more abundant ones. Last winter I subsoiled, 18 inches deep, a field previously well drained, and before horses could stand on it this spring, I sowed with artificial guano in drills made by hand, Belgian Carrot seed previously steeped in liquid manure; and in consequence of using this manual labour I have gathered a harvest of 20 tons of roots, and 11 tons of tops. Let me now, my lord, mention the success and particulars of a method, which I learned from the American translation of Burger's German work (and this will serve to illustrate the advantage of 'book farming,' when corrected by practice), of preserving the surplus leaves of our green crops as winter food for cattle. The plan I pursued was to dig a long and deep pit, say 12 feet long, 6 feet wide, and 7 feet deep, in some dry spot, or made dry by draining; then to put a bed of straw or Vetch haulm at the bottom; upon this a layer of leaves, Carrot or Mangold, was strewed a foot thick, and trampled firmly down by two or three men; then a layer of salt, at the rate of 4 lbs. of salt to every cwt. of leaves, distributed evenly; then another layer of leaves, and another of salt, until the pit was filled; then it was covered with bavins, straw, and earth, so as effectually to keep off the weather, and to be as far as possible air-tight. In a few days a violent fermentation came on and a great subsidence of the materials; the pit was re-opened and again filled as before. This morning I opened one of the pits, containing Carrot tops, to see, after three weeks' fermentation, in what state things were; the appearance was at first certainly most unpromising; it seemed to be a mass of greasy dung; but, not dismayed, I carried some to the cows and found they ate it eagerly. So I have covered up my pit again, feeling assured that when, in perhaps a month, the fermentation is over, I have a large bulk of valuable winter fodder for my milch cows. Practical men will see the value of this plan, when they bear in mind that on taking up their roots they have on their hands from 10 to 14 tons of roots per acre. But there is another mode of employing our rural population, more important perhaps than any other yet suggested. That is in the cultivation and after-management of the Flax crop, equally valuable for the fibre and the seed. Here, however, we are met with the general objection, that Flax is an exhausting crop, and its growth forbidden in gentlemen's leases. But this prejudice I believe to have no other foundation than the classical authority of a line in Virgil's first Georgic. I have the experienced authority of a gentleman at Gillingham, who has grown Flax for many years, and who declares that his best Wheat crop is after Flax! If we wish to estimate the value of a Flax crop, we must recollect the following facts (for which, as well as for all the information which I possess on this subject, I am indebted to that able gentleman, Mr. Warnes, jun., of Trimingham.) The importation of Flax (from Belgium chiefly) amounted to more than 5 millions a year—viz., a sum very nearly equal to the amount of poor-rates of all England, and the value of this fibre consists chiefly in the labour expended on it. Now, besides these 5 millions paid by England for foreign labour, 2 or 3 millions more are sent, annually, out of this country for linseed cake; and what stuff it is! I appeal to any gentleman who has examined it with a microscope, to bear witness of what incongruous and worthless materials it is, in a large measure, composed—of Mustard and refuse seeds, &c., &c. (And 'old rope,' by Mr. Farquharson, which elicited a loud laugh.) Whilst we are sending away all this money for fibre and seed, we might ourselves most advantageously be growing and manufacturing this admirable crop ourselves. In our farm houses and cottages four acres of Flax would employ from 10 to 12 hands, the whole winter months, in shelter and amidst their families. And as to the value of the seed, I have learned, by the use of 2 lbs. a day, grown on my own farm, properly ground, and diluted with boiling water poured over cut straw or chaff (consisting of straw and Turnip-tops), to feed my cows at 2½*d.* a day, and to obtain unusually rich cream for the breakfast table, and this without giving any hay. Indeed, so great a discovery do I consider this, that I mean utterly to discard in future the use of that fodder (hay), hitherto considered so indispensable for milch cows and a breeding flock. I have two cows which I call my experimental cows. I assure you that when I first had them they were miserable-looking animals; but now they have sleek coats and are in good condition, giving excellent milk. I shall be glad to show them to any gentleman who will be kind enough to pay me a visit." After other observations, the rev. gentleman said—"This, my lord, is but a most imperfect and rudimentary sketch of some of the methods whereby we can, by improved husbandry, employ our rural population to their great happiness and our own advantage. On another occasion, if we are allowed to meet another year together, I shall, I believe, be able to set forth other approved plans of engaging all our people; but I have already trespassed too long on your indulgence ('No, no'), and therefore, in conclusion, I can only lift my humble warning voice against any system which shall impress our labourers with the notion that we regard them as an incumbrance and a nuisance, instead of their being, as indeed they are, God's gift to us, and in the words of the Society's motto, which your lordship has so effectively set forth, 'Our country's dependence.'"—(The rev. gentleman then sat down amidst loud and long-continued applause.)

FARMERS' CLUBS.

Maidstone.—Sir E. Filmer spoke as follows on the allotment system here, at a late meeting of this Society:—It had been said that the worst master a poor man could have was himself, but he thought that had been fully disproved. He had 60 allotments, which had been worked for ten years, and for the last four years there had been only one defaulter; and that was the case of a poor widow, who had not her money ready at the time, but paid it within a week. To prove that the poor man was not a bad master to himself, he could give them a statement with which he had been furnished by one of his own labourers:—

Rent, 1 quarter of an acre		£0	7 6
Manure, 17*s.* 6*d.*; Garden Seeds, 1*s.* 6*d.*;			
Potatoes, 11*s.* 8*d.*		1	10 8
		1	18 2
The produce of this was as follows:—			
Potatoes, 4*l.* 1*s.* 6*d.*; Fruit, 10*s.*		4	11 8
Vegetables for own consumption		0	10 0
		5	1 8
From which deduct		1	18 2
There would be a clear profit of		£3	3 6

He went over the whole allotments afterwards, and found them much better farmed than they had been, and although he did not think the allotment system was a panacea, yet he thought it relieved the poor man from a great deal of anxiety, and taught him better his duty to himself and his master than anything else did.

Darlington.—At the November Monthly Meeting of this Club, the subject under discussion was, The proper Time for Ploughing, Preparing, and Manuring Land for Beans, and other Crops. A lengthened discussion took place, and the unanimous conclusions come to at the meeting were, that the best time for manuring, and giving the land the first ploughing is in autumn previous to the winter's frosts, after which the land should be ploughed once at least in the spring; the manure applied is best about half rotten, and the land should be ploughed deep, and kept thoroughly gripped, *i.e.* the water furrows well opened through the winter, so that no stagnant water may remain in the land. Drilling and dibbling Beans was recommended in all cases in preference to sowing broadcast, as by that means the land can be hoed and kept free from weeds whilst under crop; the Suffolk drill answers well on most soils, as does also ribbing and drilling with the barrow drill in many cases; but owing to the seed spreading more in the rows by this process, it makes the crop more difficult to hoe than when drilled with the Suffolk drill. From 18 to 20 inches was considered a good width betwixt the rows.

Dorchester.—At the annual meeting of this Society Mr. Sheridan said:—One of the objects of this and similar societies is to increase the produce of the soil; I have, with that view, made one or two experiments this year. I mixed 60 lbs. of bone-dust and 40 lbs. of sulphuric acid together, and added 400 gallons of water; the cost of this was about 10*s.* 8*d.*—4*s.* for the bone-dust, and 6*s.* 8*d.* for the sulphuric acid. The liquid was conveyed to the field in a barrel, and applied in small quantities over an acre of ground after the seed was sown; it was drilled fourteen inches apart, on ridges, with Skirving's Swede. The result has been, that I have a more abundant crop of Turnips than I have seen elsewhere in the neighbourhood, and this at an expense only of 10*s.* 8*d.* per acre; whilst the general practice amongst my neighbours, I believe, is to apply two quarters of bone-dust per acre, at a cost of 2*l.* 2*s.* I think it right to add that there is a great deal of trouble attending the application of this manure, and much caution is necessary in conveying the liquid to the field where it is to be used, as the sulphuric acid, unless sufficiently diluted, is very destructive both to wood and metal. Then again, I tried thin sowing on an acre of ground upon our hills, exposed to the S.W. wind: I sowed one bushel and a half of Marigold Wheat; the drills were ten inches apart. The result has been, where the tenant before only obtained 8½ bushels (!) from 3 bushels sown, I have reaped 11 sacks, the bushel weighing 61 lbs.

Holt.—The Exhibition (for a sweepstakes) of Swedish Turnips, grown by gentlemen in the neighbourhood of Holt, in Norfolk, took place at the Feathers Inn, on Saturday last, when the Prize was awarded to Mr. Walter Thurtell, jun., of Wighton, the six Turnips shown by him weighing upwards of 65 lbs. In growing these Turnips, various manures were used, and the highest garden culture applied, the particulars of which were detailed in a very clear and satisfactory manner by Mr. Thurtell. The other Turnips exhibited were from field culture, and weighed as follows:—

	lbs.		lbs.
By Mr. Bolding, Waborne	42½	Mr. Sheringham, Thornage	33½
Mr. Page, Barningham	41½	F. L. Astley, Esq., Burgh Hall	32
Mr. Sayers, Field Dalling	41½		
Mr. Burrell, Thornage-hall	30½	Mr. Thos. Norton, Holt	27½

Mr. Sayers also produced—

5 Carrots, weighing	16½ lbs.	2 Kohl Rabi	14 lbs.
4 roots Mangold Wurzel	81 ,,	2 Cabbages	26½ ,,

After the Show, the party, consisting of upwards of 20, spent a very pleasant evening together, when it was agreed to renew the sweepstakes for the ensuing year, and also to have another sweepstakes of 5*s.* each, to be laid out in plate, and presented to the member who should grow the greatest weight of Swedish Turnips upon a field, or part of a field, containing not less than three acres.—Mr. Sayers also offered a Prize of a Silver Pencil-case, value one sovereign, to the member who should grow in the ensuing year six plants of the Kohl Rabi of the greatest weight. Lord Hastings is a subscriber to both the above sweepstakes.

Staithwaite, Huddersfield.—At the Annual Meeting of the Earl of Dartmouth's Spade Husbandry Tenants, the prizes for Wheat were awarded to—John Sykes, who, although the land on which it was grown was an old stone quarry, had by his industry raised from a quarter of an acre, 745lbs., which was equal to 6 quarters and 2 bushels to the acre, at 60 lb. to the bushel; John Balmforth, whose produce had been 46 bushels to the acre, and C. Varley, whose produce averaged 40 bushels to the acre. On one plot of ground two crops had been raised this year; in the months of March and April Peas and Beans had been sown, which were cut in July, and produced about 30 tons to the acre of green food. Turnips were then sown, which were gathered in this day, and on calculation, will yield about 10 tons of bulb and 12 tons of top, and better Turnips need never be seen. John Balmforth read a statement of his proceedings in the various processes required by the land he had made his care. His conclusions were as follow:—

Expenditure, including labour, calculated at 2*s.* per day		£8	13 3
Total returns		35	16 9
Leaving a net profit (of about ⅛ of an acre of land!)		7	3 6

Miscellaneous.

Rowlandson on the Influence of Lime.—As the farmers of Britain and Ireland (he says in the *Journal*

of Agriculture) expend much above a million sterling yearly on lime, it must be of primary importance that the action of this manure be fully understood. He promises to point out an "unerring method" by which any ploughman may, for the merest trifle of expense, determine when lime is required by any soil! According to Mr. Rowlandson's view, "nine-tenths of the money expended on lime are an utter loss to the farmer." While occupying a large farm in Ireland he pared, burnt, and limed a portion of peat-soil, and from it raised splendid crops of Carrots, Potatoes, Turnips, &c. He pared and burnt a contiguous portion of the same peat, but gave it no lime, and the crops on it were an entire failure. He observed that the burnt but unlimed portion gave a deeper colour to rain-water than it had before burning, while, on the contrary, the heaviest rains were no more coloured on the limed part than on the most fertile loams. He next gives a familiar account of the experiments by which his views are established. He buys "two or three pennyworth of ammonia" (or hartshorn) from the druggist, takes a specimen of the barren pared and burnt, but not limed, peat soil, and another of the fertile limed peat, goes to the kitchen, procures from "the dame" two clean tall glasses, and with this "complete laboratory for the purpose," he begins by putting a portion of the barren in one glass and the fertile peat in the other, labels the glasses, covers each specimen for about a quarter of an inch with the hartshorn, and sits down to mark the result. The glass containing the unlimed specimen has its liquid soon coloured deep brown. He waits the limed specimen a little longer, but its liquid continues perfectly clear. He throws out the coloured liquid and its peat, cleans the glass, puts another portion of the same unlimed peat in it, fills up the glass with clear lime-water, goes to bed, sleeps soundly, "rises with the lark," goes to the glass with lime-water, shakes it up, and goes to his farm-work. After breakfast, he again visits this glass, tastes the contents, and finds that the water has lost its alkaline taste. He next takes oxalic acid, which he tells the ploughman is poison, dissolves a little in cold water, and pours some of the liquid from the lime-water glass into the solution. If the lime had been still dissolved in the water, the oxalic acid would have made it milky, and soon caused a white powder of oxalate of lime to fall; but all remains clear. Hence he infers that all the lime has been removed by the peat. For some time, he daily pours off the water, and adds fresh lime-water, till at length, on testing as above with oxalic acid, he observes a milky appearance, and from this infers that the peat can absorb no more lime. He now pours off the liquid from the peat, pours ammonia in its place, and lets it stand for some days, to see if the ammonia can be coloured by peat, after the peat has been saturated with lime; "but no such thing occurs." This experiment taught him to lime the other burnt lot: he did so, and had splendid crops of Mangold, Cabbage, &c. He supposes he has now fairly proved that the alkaline humates are poisonous to plants, and that lime fertilises soils, not by rendering inert vegetable matter soluble, but, on the contrary, by rendering the poisonous humic acid insoluble, in taking it from the alkali. Though his paper extends over 16 pages of the *Journal*, it is not all published, and we are not told what is his "unerring method" of determining when any soil requires lime. But as he ascribes the barrenness of soils which abound in vegetable matter "solely to the presence of free humid acid," and has already shown us how to detect this acid, we may suppose that his method is detailed in the above experiments. And as many farmers, if not many ploughmen, may wish to try his method, I shall give a brief plain sketch of the practical part of it, as I suppose he would give it himself. If the farmer wishes to discover whether one of his fields needs liming, he may take a few specimens from different parts of it, each from 2 to 4 oz. weight, put them, one at a time, moist as in the field, into a clear tall drinking glass (a quinine bottle, which may be had for 2*d.* or 3*d.* at the apothecary's, is better), cover the soil for about a quarter of an inch with common "spirit of hartshorn," and when it has stood a little, observe whether the liquid is coloured brown, and pour it off cautiously (withholding the soil) into another glass containing clear lime-water. If ammonia has taken any "humic acid" from the soil, the whole lime-water will now become turbid, and a dirty brown flaky precipitate gradually falls to the bottom. This, according to Mr. Rowlandson, gives clear evidence that the soil needs lime, and if the ammonia causes no brown turbidity in the lime-water, the soil does not need lime. I do not vouch for the uniform accuracy of this method; but as the trial is so easily made, and to reflecting farmers may lead to important inferences, I think many might try it, especially for cold, clayey, and peaty soils. To prepare the lime-water, take a large clean bottle, put in it a spoonful of slaked lime, fill the bottle nearly to the top with rain-water, agitate, fill up, cork, and set it aside for several hours to let the lime settle. It requires to be kept closely corked to exclude carbonic acid.—*P. Garden, Glenæ, in the Dumfries Herald.*

Management of Farm-yard Manure.—The best-constructed farm-yard and management of manure I ever saw is Mr. Spooner's, the lately elected M.P. for Birmingham. This gentleman has a farm of from 150 to 200 acres, situated near the city of Worcester, in the highest state of cultivation, on which he grows the most luxuriant crops, without having expended a shilling for manure for many years (with the exception of a trifling sum for those lately-introduced novelties, by way of experiment), but has sold much farm-yard manure to his neighbours, not knowing how to dispose of it on the farm. Although he does not possess an acre of watered meadow, he has generally hay for sale. The farm-yard is an oblong square, the back of the house occupying the south end; at the south-west corner is the piggery; the west side a cow-house, containing standing for upwards of 20 milking cows, which is kept full all the year round; in the summer they are fed on Tares, Lucerne, and Grass; in the winter a little hay is given them in the morning, Swedes or Mangold at noon, and as much bruised Gorse (Furze of one year's growth) as they will eat. They have hay in lieu of Gorse on Sundays, as it is necessary for the Gorse to be consumed on the day on which it is prepared; at the back are sheds for storing roots and the hay-stack yard. At the north-west corner the Gorse-mill is erected, communicating with a passage to the heads of the cattle, for the purpose of feeding. At the north end are the barns, with the rick-yard behind. On the east side are the stables and sheds, a road at the back, and an entrance adjoining. In the centre is the manure-pit, six or eight feet deep, covered by a roof, and surrounded by a dwarf wall, so as to prevent the possibility of any water getting into it. It is entered by an inclined plane, wide enough to back in a cart, opposite the approach to the yard. Into this pit the dung from the stables and cow-house is promiscuously thrown; in the middle of the side contiguous to the latter is a well and a pump, which receives the drainage therefrom and the stables, which is pumped up and spread over the manure by a shute. The surplus liquid that is not absorbed is drawn off by means of a drain under the barn into a receiving well in the stack-yard, where it is pumped up into the liquid manure-cart, and drawn out on the mowing-ground as soon as the Grass is cut, until such time as it is laid up again; in the spring it is otherwise disposed of on headlands and heaps of soil. Liquid and solid manure, prepared in the way above described, preserves all its nutritious qualities; the one is not diluted by water, and the other not suffered to deteriorate by over-heating, and is of treble the value of that made in the common manner.—*W. B.—Bell's Weekly Messenger.*

Rape for Winter Feeding.—What must the farmer resort to for winter feeding, now that the Turnips have utterly failed in many places? I answer, let him still try Rape Kale on his Turnip-field, without ploughing afresh. The ground may be harrowed and then sown; or the patches of ground where Turnips have failed may be sown with Rape-seed after a shower; or steep the seed and let it dry so that it may not clog in the sowing. If after early Potatoes, the following plan has been recommended:—As you lift your Potatoes, sow Rape-seed, 14 lbs. or 15 lbs. per acre, not later than the end of this month (Aug.). The price of the seed will not exceed 5*s.* per acre. If the season is favourable, you may lay on two and a half scores of sheep to 4 acres, about the middle or end of October. With the addition of the produce of half an acre of Turnips thrown among the Rape, you will have your sheep in first-rate condition for the spring market. In one similar instance, which came under my observation last season, the profit per score amounted to 9*l.* 10*s.*, not deducting the price of seed. The land will be in excellent order for the reception of spring Wheat, which will be found to yield better, and the quality of the grain will be much superior to that of winter Wheat, which is unsuited to early soil. Turnips have been recommended on early soils after Potatoes, but will not suit a cold situation. I would recommend farmers to sow Rye and Vetches upon their stubbles for spring feeding: they will find this a valuable assistant where the Turnips have failed. — *Correspondent of Shrewsbury Chronicle.*

The Management of Heavy Soils.—Farmers have often remarked, that lime does least good to cold, wet, clayey, and peaty soils, when spread on them in autumn; and that it can be profitably laid on them only in the early part of the season, when in their driest state. The reason of this is also plain: lime is dissolved more largely in very cold water than in warmer water. The rains of winter thus dissolve much of it, and carry it off. When Turnips have remained on clayey soils till spring, the crop has in part sheltered the soil from frost. It has been farther consolidated or bound by the winter rains, and the exclusion of air; and when in this wet state sheep are put on it, say in March, they soon reduce it to mortar: in this state it is ploughed, and rises in adhesive lumps resembling subsoil. The advanced period of the season demands that it be sown as soon as the harrows can break the top of the clods. The Oat-seed has thus a thin scraping of coarse soil about it; but at the depth of only 2 or 3 inches, the lumps of solid clay deny admission to the roots. This evil is much increased when the advanced period of the season has rendered it necessary to sow Barley instead of Oats. As this seed requires a looser soil and a finer tilth than Oats, it is not to be wondered at if it fail in such cases, especially where much drought follows the stage of germination. Only the strongest plants in the best positions come forward; stolling is prevented at the proper season; a thin yellow blade is all that can be seen in May and June: the Potato ground on the same soil affords a striking contrast. If July and August are moist, after-growths continue to rise, and a crop deficient in quantity and unequally ripened is the result. Too many evidences of this, both in Barley and Oats, were afforded by the crop, lately reaped after Turnips. If Turnips must be eaten by sheep on heavy soils, the fields ought to be cleared in time for their being all ploughed by Christmas. But I raise and store all my Turnips grown on heavy and medium soils, and give them to stock on the pasture fields, in the court, and in the byres, as good dung is literally given for the Turnips; this keeps the soil open in winter, and the dung is thus farther prepared for next crop. I find it most advantageous in this case not to plough up the dung till the approach of seed-time. On light soils it is highly advantageous to have the ploughing deferred, and, of course, the eating of crop as long as possible.—*P. Garden, Glenæ, in the Dumfries Herald.*

Notices to Correspondents.

*** Will the author of the letter on Smithfield be good enough to excuse our delaying its publication for another week?

After-Grass.—*A. L.*—If you have a witness who can prove the agreement as stated, although only a verbal one, you may recover the amount agreed on. *W.*

Burnet.—*L. W.*—It is to be sown just as Sainfoin, using about a bushel of seed per acre. You will not find it worth your while to cultivate it.

Drainage.—*W. F. G. F.*—If the lines you have drawn in your little plan are those of greatest descent on the field, they are precisely those which you should mark out for the drains. It will take about 1600 tiles, 18 inches long each, to drain an acre, at 20 feet apart. Cover the tiles with the turf reversed, and then fill in the rest any how.

Farm Accounts.—*G. B. M.*—Swinhorne's "Farmer's Account Book" is pretty well; but, like all of its class, it is imperfect. We shall return to this subject.

Gas Lime.—*G. B. M.*—This is imperfect hydro-sulphuret of lime. When exposed to air, it is gradually converted into sulphite, and ultimately into sulphate of lime or gypsum; three or four cwt. per acre is a plentiful application: 7*s.* 6*d.* a chaldron have been given for it.—*A Subscriber, Andover.*—It is useful as a manure, because, after long exposure to the air, it becomes sulphate of lime or gypsum, the fertilising properties of which everybody knows. You had better not mix it fresh. Three or four cwt. per acre spread now on the land, and ploughed under in spring, would be as effectual as a larger quantity; and this would be a better way of using it than the plan you propose of mixing it with bones.

Gorse.—*Nice.*—Can any one give us information respecting the Furze that has no thorns? It is sometimes called Irish Furze.

Murrain.—*Maillew.*—We cannot give advice for the diseases of cattle, unless the symptoms are described. The term "murrain" is used in various districts to designate different and distinct diseases.—*W. C. S.*

Sheep Farming, Manure, &c.—*E.*—Your object clearly is, that the tenant should buy as much of as valuable manure as the hay would produce were it consumed upon the land. If he knows the value of manure he will be able to do this for less than three-fourths of the value of the hay. One-half its value so spent would, we think, be quite a sufficient security for the fertility of the land. In the country, here, we should say that *the whole* of the value of the straw, if allowed to be sold, should be spent in manure; but near town, where this part of the corn crop is so much more valuable, and where rent, on this and other accounts, is so much higher, this, we presume, would hardly be a fair arrangement. Three-quarters of its value spent in manure would probably be more just.—If your farm of 150 acres, under a five-shift course of cropping, be in good cultivation, and capable of yielding, on an average, 22 tons of roots, 30 cwt. of Clover hay, and 25 cwt of straw, per acre; then, besides your cow and six fatting beasts, you ought to be able to keep a flock of 200 breeding ewes, which we may suppose to yean 220 lambs every spring; of which 50 may be sold fat by July, and 130 may be sold fat as shearlings in the month of May following, along with 20 old ewes, whose places may be supplied by 20 of the ewe-tegs; or, as we should then call them in this part of the country, *chilver tegs*, or *theaves*; the remaining number of the lambs go to balance the profit and loss account of disease and death. The following is our calculation:—The produce of the farm will be off 60 acres of grain crop, 30 acres of roots, 30 acres of one-year-old Clover, and 30 acres of two-year-old Clover. The first will yield 75 tons of straw, the second 660 tons of roots, the third 45 tons of hay and 30 acres of aftermath, and the fourth 30 acres of pasture. This last will keep 170 ewes, and so many of their lambs as remain, till the 1st of October. The aftermath is equal to the keep of the cow and six horses in Clover, and also of 30 ewes and lambs till the same period. We suppose, however, 50 lambs to be sold in July, so that on the 1st of October there will be 6 horses, 1 cow, 6 fatting beasts, 200 ewes and 150 tegs; to keep which till the 1st of May there are 660 tons of roots, 45 tons of hay, 73 tons of straw; and 15 tons of oilcake will need to be bought. This will be consumed as follows:—

	Hay.		Roots.		Oil-cake.	
	tons.	cwt.	tons.	cwt.	tons.	cwt.
6 horses will eat daily, besides Oats and straw, 5 lbs. of hay, 20 lbs. of roots; equal to	2	10	10	0	—	
1 cow, at 12 lbs. of hay and 40 lbs. of roots daily; equal to	1	0	2	6	—	
6 beasts at 5 lbs. of hay in their chaff, 60 lbs. of roots, and 6 lbs. of oilcake daily, till 20th Feb.; equal to	1	15	21	0	2	
200 ewes, at 2 lbs. of hay each, daily, and 12 lbs. of roots, till 1st Feb.; then 2 lbs. of hay and 30 lbs. of roots	33	10	360	0	—	
150 tegs, at ¼ lb. of hay chaff, daily, and 1 lb. of oilcake, and 20 lbs. of roots; equal to	6	5	250	0	12	18
	45	0	644	6	15	0

Supposing all this stock to be kept under shelter, 40 tons of straw may be needed for litter and food, leaving 25 for sale.

Turnip Machine.—*M. Soul.*—We have your drawing by us, and shall call attention to your machine, when, in the course of our articles on Agricultural Mechanics, we touch on this subject.

Wheat.—*G. B. M.*—Bellevue Talavera will probably suit you well.

Erratum.—For the word "feeding," in the 2d line from the top of the 2d col., at page 857, read "breeding."

HOPS, Friday, Dec. 27.

We have had a good trade in Hops this week, and there is a steady demand for Pockets, which we think must soon go considerably higher in price.

Farnham, Bo[illegible], Mid-Kent

SMITHFIELD, MONDAY, Dec. 23.—Per stone of 8 lbs.

Beasts, Sheasters, &c.	4s	0 to 4s	6	Best Downs & Half-breds	4s	4	8
First Quality Mutton	3	10	4	0	Best Long-wools	3	8	4
Second quality Mutton	3	6	3	8	Downs and second quality	3	4	3
Calves	4	0	4	8	Pigs	3	4	3

Beasts, 1319; Sheep, 16,480; Calves, 194; Pigs, 290.

As it must be soon to Christmas day, scarcely any business is transacted in our Market to-day. Our supply of Beef is tolerably good, and as the best qualities maintain late rates; but there being no stock an abundance of buyers, reduction in price must be submitted to to effect sales to any amount. The trade amongst the Mutton is even slower than for the Beef. Lambs is very little indeed wanted, and a very great many remain unsold. Calves are but very few Calves here to day, which are sold dearer. Pork trade continues heavy.

FRIDAY, Dec. 27.

Again we have a kind of holiday Market; the large supply of the "Great Market" is not yet forgotten; indeed, since then the quantity has been large for the season. For what little business is done, both in Beef and Mutton, the prices continue the same as Monday, except in the second-rate qualities, which are a little lower. Veal is short, and consequently dearer; several good Calves have made fully and we think a little over 5s per 8 lbs. The second quality also finds a much more ready sale, at a proportionable rise in price. Pork trade continues steady.

Beasts, 633; Sheep, 8160; Calves, 54; Pigs, 227.

61, West Smithfield.

MARK-LANE, MONDAY, Dec. 23.

THERE was a fair supply of Wheat from the near counties this morning, which met a slow sale at last week's prices; business in Foreign continues limited, but its late value is fully supported. Barley, Beans, and Peas maintain our quotations. Oats are still very scarce, and where sales are effected, extreme rates are obtained.

FRIDAY, Dec. 27

THE arrivals of Corn and Flour during the week have been very moderate, and the attendance at market this morning was small; we observe no alteration in the value of either English or Foreign Wheat; the only bonded transaction we have heard of is the sale of 2000 barrels of American Flour at 18s per barrel, and there was some inquiry for low Baltic Wheat. Barley, Beans, and Peas fully maintain the quotations of Monday. Being still without any arrivals of Irish Oats, factors are enabled to obtain a trifling advance.

KINGSCOMB AND LAY.

COVENT GARDEN, DEC. 28.—The Market has been well supplied during the week with vegetables of almost every kind, and the quantity of fruit has also been sufficient to meet the demand. Among Pine Apples we noticed some handsome specimens, which are offered at nearly the same prices as are quoted in our last report. Grapes, which chiefly consist of foreign sorts, are also selling at last week's prices. Apples are plentiful, but the demand for them is not great. Among Pears, good samples of Glout Morceau and Winter Nelis, which are the principal dessert varieties in the market at present, are selling at about 8s. per half sieve. Nuts are scarce, and consequently realise high prices. Oranges, of good quality, are abundant, and Lemons are also sufficient for the demand. Of vegetables, there are plenty of most sorts; Cauliflowers are, however, scarce; and Broccoli, owing to the late frosty weather, is not so plentiful; but Cabbages, Brussels Sprouts, and Savoys are good in quality and abundantly supplied; Carrots, although somewhat inferior in quality, are plentiful; Turnips are very good, and sufficient for the demand. A considerable quantity of American Shallots are in the market, and being good in quality they meet with a tolerably ready sale. Rhubarb, Asparagus, and Sea-kale, are offered at last week's prices. Celery is plentiful and good. Endive, Lettuce, and other kinds of salading are pretty plentiful. Among cut flowers we noticed Euphorbia jacquiniflora, Bignonia venusta, Coronilla glauca, several species of Cape Heath, also Camellias, Cinerarias, Acacias, Amaryllises, Azaleas, Chrysanthemums, Tulips, and Roses.

FRUITS.

Pine Apple, per lb., 4s to 7s	Oranges, per dozen, 6d to 1s 6d
Grapes, Hothouse, p. lb., 2s to 5s	— per 100, 3s to 10s

Shallots, per lb., 6d to 8d	
Capsicums, per 100, 4s to 8s	

THE BEST AND MOST DURABLE ROOFING,
FOR BUILDING AND GARDEN PURPOSES.

BY HER MAJESTY'S  ROYAL LETTERS PATENT.

THE PATENT ASPHALTE FELT for ROOFING,
AS IMPROVED BY
THE ORIGINAL INVENTOR AND PATENTEE,
AND NOW IN USE AT
THE ROYAL HORTICULTURAL SOCIETY'S GARDENS AT CHISWICK,
Can be had only by applying to
THOS. JOHN CROGGON, 2, INGRAM-COURT, FENCHURCH-STREET, LONDON.

The above Material has been used and approved of by the Nobility, Gentry, and Agriculturists generally, as a ROOFING and COVERING to SIDES of FARM BUILDINGS.

The Felt is perfectly impervious to rain, snow, and frost, and being a non-conductor, it has been proved an efficient PROTECTIVE MATERIAL TO PLANTS.

The price of the Felt is ONLY ONE PENNY PER SQUARE FOOT, being much less than half the expense of Slates, Tiles, &c., and from its LIGHTNESS, WARMTH, and CHEAPNESS is particularly well suited for Hothouses, &c. A discount allowed to the Trade. THOS. JOHN CROGGON, 2, Ingram-court, Fenchurch-street, London.

Patent Asphalte Felt Works, Dec. 28

IMPROVED ROOFING FELT.

McKIBBIN'S PATENT ROOFING FELT

Is particularly applicable as a Substitute for Slate, Zinc, Tiles, Thatch, and other articles used for Roofing, from its Economy, Durability, and Lightness. It is quite impervious to wet and damp, resists the heat of the sun, and is a non conductor of heat or cold. Besides the economy in repairs, the timber where it is used may be so light as to save its whole expense. It requires no other coping, and by attention to printed directions may be applied by a common labourer. It is free from breakage and contraction, like zinc, and requires neither painting nor coating. It is now in very general use for Roofing Houses, Verandahs, Sheds, Workshops, Ropewalks, Railway Stations, Icehouses, &c. &c., and for protecting Plants, covering Garden Frames, Corn, and Hay Ricks, the top and sides of Sheep-folds; and to Emigrants it provides a cheap, warm, durable, and portable Roof.

This Improved Roofing Felt is much more durable than the common Felt, made in lengths, not being subject, like it or other materials in continuous lengths, to be stripped by storm; and being fastened down at the overlaps only, the wet cannot percolate through the nail-holes.

TESTIMONIAL.

London, Nov. 1, 1844.

H. C. BOWDEN, Esq., Agent for McKIBBIN'S Roofing Felt.

It is with much pleasure I add my humble testimony to the superiority of your Felt over any other preparation of the kind with which I am acquainted. This Testimony I give with the greater cheerfulness from the many reports I have heard in its favour, and from the likelihood of its being used extensively in Agricultural purposes. I shall not fail to notice it in my Lectures when on the subject.

(Signed) JOHN ROBINSON, M.B., Senior Lecturer on Chemistry, &c., as applied to Agriculture and Rural Economy in this Kingdom.

Sold in Sheets 32 inches by 20, at 5d. each (being less than 9s. 6d. per square of 100 feet).

Apply to H. C. BOWDEN,
Agent to the Manufacturers,
No. 18, East India Chambers, Leadenhall-street, London.

CHEAP AND DURABLE ROOFING.
AND THE BEST REGISTER OF FROST FOR GARDEN USES.

BY HER MAJESTY'S  ROYAL LETTERS PATENT.

TO GARDENERS, NURSERYMEN, AND OTHERS.

F. M'NEILL & CO., of Lamb's Buildings, Bunhill-row, London, Manufacturers, and only Patentees of IMPROVED PATENT ASPHALTED FELT, for Roofing Houses, Sheds, Verandahs, &c., and particularly for COVERING GARDEN FRAMES, TO PROTECT PLANTS AGAINST THE EFFECTS OF THE FROST, beg to call the attention of Gardeners and others to their superior article, *which has been exhibited at the Great Agricultural Shows of England, Scotland, and Ireland, and obtained the Prize for being the best and cheapest article for roofing, &c.* It has been tested in the gardens of several noblemen and gentlemen in the neighbourhood of London, and in different parts of the country, to whom reference can be made. This Felt is composed of the strongest and most durable materials, and is saturated with the BEST OF ASPHALTE OR BITUMEN, (THE SAME AS SELECTED AND USED BY SIR ISAMBERT BRUNEL FOR THE THAMES TUNNEL, BEING FOUND THE MOST ELASTIC AND EFFECTIVE REGISTER OF WET.) NO OTHER FELT HAS THIS ASPHALTE BUT F. M'NEILL & CO.'s, and which renders it impervious to rain, snow, and frost, and a non-conductor of heat and sound. Its advantages are Lightness, Warmth, Durability, and Economy.—Price ONLY ONE PENNY PER SQUARE FOOT.

Samples, with directions for laying on, and testimonials as to its merits, sent free to any part of the town or country.

PATENT FELT MANUFACTORY (THE ONLY FACTORY IN GREAT BRITAIN WHERE THE ABOVE DESCRIPTION OF ROOFING IS MADE), LAMB'S BUILDINGS, BUNHILL ROW, LONDON.

A Sample Roof and Frame to be seen at the Factory, and a Discount allowed to the Trade.

TO COLONISTS, EMIGRANTS, &c. — Mrs. MARY WEDLAKE, widow of the late THOMAS WEDLAKE, at 118, FENCHURCH-STREET, CITY, informs Emigrants and others that she continues to manufacture those Agricultural Implements for which her late husband was so extensively patronised by the Settlers of South Australia, Van Diemen's Land, Swan River, New Zealand, and other British Colonies. The following articles, made in a very superior manner, are kept on sale at the London Warehouse, viz.:—

Patent Hayemaking Machines	Flour-Mills—Bean-Mills
Dressing Machines	Patent Essex Ploughs, 30 sorts
Patent Chaff-cutting Machines	Subsoil Ploughs [Colonies
Oil-cake Crushers	Threshing Machines for the
Double action Turnip-cutters	Drills of all kinds—Scarifiers
Railway Wheels	Vacuum Pumps.

Please to be particular in the address, MARY WEDLAKE, 118, Fenchurch-street, London.

STOOPING of the SHOULDERS and CONTRACTION of the CHEST are entirely prevented, and gently and effectually removed in Youth, and Ladies and Gentlemen by the occasional use of the PATENT ST. JAMES'S CURVE EXPANDER, which is light, simple, easily employed overtable or invisibly, without bands beneath the arms, and by Mr. constraint, or impediment to exercise. Sent per on full particulars on receiving a postage-stamp. E. BURTON, 49, Tavistock-street, Strand, Lon-

REAL SHEFFIELD PLATED DISH COVERS, at prices hitherto unattempted. THOMAS WEST, 18, Ludgate-street, London, having received a large supply direct from the manufactory at Sheffield, offers the best Meat Dish Covers, 22 Tallow.—Cottage Pattern—1 Cover of 20 inches, 2l. 12s.; 1 do. of 18 inches, 2l. 3s.; 2 do. of 14 inches, 4l. 8s.; the set of 4, complete, 11l. 10s. ONLY. Double Dome Pattern—1 Cover of 20 inches, 4l. 16s.; 1 do. of 18 inches, 3l. 12s.; 2 do. of 14 inches, 5l. 8s.; the set of 4, complete, 14l ONLY. In noticing the prices of the above goods, T. W. ventures to assert they are superior to many advertised at a much higher price. Best Wrought Silver Spoons and Forks as usual, Fiddle Pattern, 7s. 2d. per oz. Queen's Pattern, 7s. 4d. per oz. Superior Watches and Plain Gold Jewellery, cheaper than any house in London. West's Hand-book, with 100 Engravings, and full of useful information, is just published, and may be had gratis, and post free, on application to T. West, Silversmith, 18, Ludgate-street, London.

ELECTRO-PLATING AND GILDING.—OLD PLATED GOODS RESTORED and made equal to new by Messrs. ELKINGTON and Co.'s Patent Process. This process being carried on in London only by Messrs. Elkington and Co., it is particularly requested that all goods may be forwarded direct to their establishments, 22, Regent Street (corner of Jermyn-street); or 45, Moorgate-street, City. New Goods plated upon White Metal in great variety. Books of Prices and Drawings sent to all parts of the Kingdom and abroad free.

PATENT ELECTRO-PLATED AND GILT ARTICLES in every variety, at the Establishments of the Patentees, ELKINGTON AND Co, West End—22, Regent-street, corner of Jermyn-street; City—45, Moorgate-street. The Patent Electro processes being extensively adopted under their licence, the Patentees beg to state that they confine their own Manufacture to goods of a superior and warranted quality only, which invariably bear their mark, "E. and Co.," under a crown. Old articles replated and gilt.

BUTTER MADE IN TEN MINUTES.—Much time and labour will be saved by the use of the SUSSEX CHURN, manufactured solely by GREEN and HALE, late Attwood, Wimble, and Warner, Lewes. This Churn being made entirely of block tin, the necessary degree of temperature can be given to the cream by placing the Churn in a pan of hot or cold water, which insures the butter coming in ten or twelve minutes at all seasons of the year. The simplicity of its construction, and the facility with which it may be cleaned, are no inconsiderable advantages over those now in common use.

Sizes .	No. 00	0	1	2	3
To Churn .	2½lb.	4lb.	7lb.	14lb.	28lb.
Price with pans	18s.	20s.	25s.	32s.	40s.

Delivered (carriage paid) to any part of London.

N.B.—Pans for making clouted cream.

London Agents:—Benham, 19, Wigmore-street, Cavendish-square; Bailey, 71, Gracechurch-street; Yates, Arthur-street East; Deanes, London Bridge. Export Agents, Barnes and Co., 109, Fenchurch-street.

LOANS.—TO FARMERS AND OTHERS.—The sum of 20,000l., and several smaller amounts not less than 150l., to be advanced upon Leasehold or Freehold Property, Reversions, Money in the Funds, Annuities, Life Interests and good Personal Security, or upon Assignment of Farm Stock.

Apply to Mr. MULLINS, St. Michael's Chambers, St. Michael's-alley, near the Royal Exchange, Cornhill, London; if personally, between the hours of 11 and 3 o'Clock. Letters pre-paid.

HEAL AND SON'S LIST OF BEDDING.—Containing a full description of weights, sizes, and prices, by which purchasers are enabled to judge the articles that are best suited to make a good set of Bedding, sent free by post, on application to their establishment, the largest in London exclusively for the manufacture and sale of Bedding (as Bedsteads or other furniture being kept). HEAL AND SON, Feather Dressers and Bedding Manufacturers, 196, opposite the Chapel, Tottenham Court Road.

LINGHAM, BROTHERS, BIRMINGHAM.—MANUFACTURERS of the IMPROVED MENOGRAPH, or PERMANENT LABELS, for Garden-borders, Flower-pots, &c. In Boxes of One Hundred each.

The above Labels have been manufactured by LINGHAM, BROTHERS, for the last five years with increasing demand, and acknowledged by those parties who have used them as superior to anything of the kind before offered to the Public, and for neatness, durability, and cheapness, have superseded all other kind of Labels for Horticultural purposes.

Sole Agents in London:—George and John Dean, Horticultural Implement Warehouse, opening to the Monument, 46, King William-street, London-bridge.

FOR WINTER WRAPPERS, GREAT-COATS, AND OUT-SIDE GARMENTS OF ALL KINDS, SEE

BERDOE'S VENTILATING WATERPROOF CLOTHING ESTABLISHMENT, 69, Cornhill, where an inspection is confidently invited of a large and superior stock of first-rate garments of the above description at reasonable charges, and really waterproof. Also of Berdoe's well-known FROCK for all Seasons, (which has stood the test of more than 6 years' extensive trial, and completely supersedes the "Macintosh"), SHOOTING JACKETS, &c. The above made to measure at same charges in a few hours.

W. BERDOE, Tailor, Waterproofer, &c., 69, Cornhill, (North side.)

NEWSPAPER OFFICE, 15, Coventry Street, Haymarket, London.—Established upwards of 30 years.

T. MUDIE and SONS, Agents for the supply of the GARDENERS' CHRONICLE and AGRICULTURAL GAZETTE, forward that and all the other London Newspapers (a correct list of which may be had on application), with the strictest regularity to all parts of the Kingdom, and to the Colonies, free of postage; and by the morning mails if requisite. T. M. and SONS beg to state that they pay the entire address of their Customers on the wrapper when ordered for six months or longer.

Containing 36 Plates, elegantly bound, One Guinea,

FISHER'S DRAWING ROOM SCRAP-BOOK "Comes forward with claims which must secure for this deservedly popular Annual honourably won in preceding years, which it has fairly yet chaste and tasteful. The engravings The binding is thirty-six), and finely executed, and the literary are numerous portion by Mrs. Ellis's pure and graceful pen."—*The World*.

Containing 16 Plates, handsomely bound, 6s.,

THE YOUNG LADY'S AND GENTLEMAN'S ANNUAL—THE JUVENILE SCRAP-BOOK, "is judiciously adapted to amuse the fancy, inform the mind, and improve the morals of the young reader. As a Christmas present, its numerous beautiful engravings, and its elegant binding, invest it with strong claims to preference."—*The General Advertiser*.

FISHER, Son, and Co., the Caxton Press, Angel Street, Newgate Street, London.

PUNCH'S ALMANACK FOR 1845 is now ready for the public. One of the most prominent features of the ALMANACK is

A Pictorial Chronology for 1844,

ILLUSTRATIVE OF

TAYLOR and WALTON, and all Booksellers

UNIVERSITY COLLEGE HOSPITAL.—The favourable consideration of those benevolent persons who at this festive season seek for opportunities of heightening their own social enjoyments by the exercise of their power to relieve the sufferings of others is earnestly supplicated in behalf of this Charity

The unusual severity of the early winter, and the severeness, not only of the destitute sick of the neighbourhood, but of poor persons afflicted with disease in distant counties, for the advice and treatment of the medical officers and attendants of this Hospital, have recently occasioned a great increase in the number of patients, and the consequent augmentation of expense, which the funds of the institution are but ill able to bear

Under such circumstances the attention of the benevolent is requested with confidence to this appeal for their assistance

The number who annually receive relief at this Hospital is nearly 1 000 The expense amounts to about 4 000*l* of which the principal portion namely, 2800*l*, is derived from the fees of students for attendance on the practice of the medical and surgical officers, by whom they are devoted to the maintenance of the Hospital The annual subscriptions now obtaining for a late splendid and commodious addition, exceed 600*l* After allowing for casual donations, a deficiency of about 1000*l* has yearly to be provided for

The Hospital, as it at present exists, is calculated for the reception of 30 more in patients than it actually contains, and it is the want of these additional beds alone which prevents the admission of that additional number The ground for a second wing to the Hospital having been, while such a wing, if the means of erecting, furnishing, and maintaining it existed, would allow of a further increase of in patients

The Committee take this opportunity of acknowledging the following contributions recently received —

DONATIONS.

Dec 23, 1844 WILLIAM JOYCE, Clerk to the Committee.

SEASONABLE FESTIVITIES.—The galaxy that reigns supreme at this festive season, when friends and lovers assemble at the social board, or whirl in the giddy maze of the dance, induces both sexes to be more than usually desirous of shining in personal attraction, and to devote a greater share of attention to the toilet. It is at this particular season, that the VIRTUES and SINGULARLY HAPPY PROPERTIES OF THOSE AUXILIARIES OF PERSONAL BEAUTY, ROWLAND'S KALYDOR, ROWLAND'S MACASSAR OIL, & ROWLAND'S ODONTO, shine pre-eminent in their power; while the *white* and *fair like neck*, the *rich luxuriant tress*, and the *Pearly set of Teeth* form admirable trophies of their UNRIVALLED QUALITIES! The august Patronage conferred by our Gracious Queen, and the several Sovereigns of Europe, together with the Beauties which adorn the circles of Princely and Regal Magnificence, and the confirmation by experience of the infallible efficacy *of these excellent restorative Specifics*, have characterized them with perfection; and given them a celebrity unparalleled As presents for both sexes, none can be more recommendatory, or more now in general use

Ask for "ROWLAND'S" Articles. All others, under similar names, are SPURIOUS IMITATIONS!!!
